red crystals.— $C_8H_4Br(NO_2)<\begin{smallmatrix} CO_2O \\ O \end{smallmatrix}>Pb$ : nearly insoluble pp. (Lellmann a. Grothmann, *B.* 17, 2729).

**Bromo-nitro-o-oxy-benzoic acid**

$C_8H_4Br(NO_2)(OH)CO_2H$  [3:5:2:1]. [222°]. Colourless needles. V. sol. alcohol, ether, and hot water. Formed by bromination of nitro-salicylic acid in acetic acid solution.

**Salts.**— $A'_2Ba$  4aq: long yellow needles.— $A'_2Ca$  6aq: yellow prisms (Lellmann a. Grothmann, *B.* 17, 2724).

**Bromo-nitro-o-oxy-benzoic acid. Methyl**

**derivative**  $C_8H_4Br(NO_2)(OMe)(CO_2H)$ . From methyl bromo-isopropyl-phenyl oxide and  $HNO_3$  (S.G. 1:3) (Perrajoner, *G.* 16, 420). A di-bromo-nitro-o-oxy-benzoic acid is also formed.

**Bromo-nitro-p-oxy-benzoic acid. Methyl**

**derivative**  $C_8H_4Br(NO_2)(OMe)(CO_2H)$  [1:3:2:5]. [182°]. *Bromo-nitro-anisic acid*. Formed by nitrating bromo-anisic acid.

**Ethyl ether**  $EtA'$ , [85°]: needles (Balbiano, *G.* 14, 241).

**DI-BROMO-DI-NITRO-DI-OXY-DI-PHENYL SULPHONE**

$C_{12}H_8Br_2N_2SO_2$ , i.e.  $(C_6H_4(NO_2)(OH)Br)_2SO_2$ , [285°]. From di-nitro-di-oxy-di-phenyl sulphone in  $CS_2$  and Br (Annaheim, *B.* 9, 660). Yellowish needles.— $C_{12}H_8Br_2N_2SO_2$  2aq: orange needles.

**BROMO-NITRO-OXY-PIPERIDINE- $\nu$ -CARBOXYLIC ETHER**

$C_{12}H_{13}Br(NO_2)(OH)N.CO_2Et$  [157°]. Colourless prisms; sol. alcohol. Formed by the action of Br in  $HOAc$  on nitro-dehydropiperidine- $\nu$ -carboxylic ether (Schotten, *B.* 16, 616).

**BROMO-NITRO-PHENANTHRENE  $\nu$  PHENANTHRENE.**

**BROMO-o-NITRO-PHENOL**

$C_6H_3Br(NO_2)(OH)$  [1:4:3]. [41°]. Formed, together with the following body [88°] by boiling (1, 3, 4)-bromo-di-nitro-benzene with aqueous KOH (Laubenheimer, *B.* 11, 1160). Prisms; volatile with steam.— $NaA'$ : scarlet needles.— $BaA'_2$ aq: red needles, sl. sol. water.— $CaA'_2$  2aq.  $AgA'$ .

**Bromo-o-nitro-phenol**  $C_6H_3Br(NO_2)(OH)$  [1:3:4]. [88°].

**Formation.**—1. From *p*-bromo-phenol and  $HNO_3$  (Hübner a. Branken, *B.* 6, 170; Körner, *G.* 4, 388).—2. From *o*-nitro-phenol (45g.) and Br (52g.) (Brunck, *Z.* 1867, 203).—3. From bromo-di-nitro-phenol (*v. sup.*).

**Properties.**—Yellow monoclinic laminae (from alcohol)  $\alpha:b:c = 2.941:1:1.625$ .  $\beta = 61^\circ 2'$  (Arzruni, *Z. Kryst.* 1, 436); may be sublimed; v. sol. alcohol and ether, slightly volatile with steam. Reduced by Sn and HCl to bromo-amido-phenol (Schütt, *J. pr.* (2) 32, 61).

**Salts.**— $Na(C_6H_3BrNO_2)$ : red needles with golden-green lustre, v. sol. water.— $KA'$  2aq.— $BaA'_2$ — $AgA'$ .

**Methyl ether**  $C_6H_4Br(NO_2)OMe$ . [88°]. From the silver salt and MeI by boiling; or from the potassium salt, MeOH and MeI at 110°. Needles. V. sol. hot alcohol or hot ether, v. sl. sol. water (Staedel, A. 217, 55; B. 11, 1750).

**Ethyl ether**  $C_6H_4Br(NO_2)OEt$ . [13°] (S.); [47°] (H.). From the potassium salt, EtI and alcohol at 100°. Formed also by nitrating o-bromo-phenetol.

**Benzyl derivative**  $C_6H_4Br(NO_2)(OC_2H_5)$ . [81°]. Yellow needles. Insol. water, v. sol. alcohol and glacial acetic acid, sl. sol. benzene, ether or chloroform (Roll a. Hölz, J. pr. [2] 32, 57). Reduced to bromo-amido-phenol, when treated with Sn and HCl, benzyl chloride splitting off.

**Bromo-m-nitro-phenol**  $C_6H_3Br(NO_2)(OH)$  [73.1]. [147°] (L.); [110°] (P.). Prepared by bromination of m-nitro-phenol (Pfaff, B. 16, 612; Lindner, B. 18, 612). Yellow needles. Sublimable. Sl. sol. hot water,  $CS_2$  and petroleum-ether, insol. cold water. On reduction with tin and HCl it gives m-amido-phenol, the Br atom being eliminated.—KA' 2aq: red crystals, sol. water and alcohol.—NaA' aq: yellowish-red crystals, sol. water and alcohol.—BaA' 4aq.

**Methyl ether** A'Me: [101°]; white needles, v. sol. alcohol and ether, on reduction with tin and HCl it gives m-anisidine.

**Ethyl ether** EtA': [57°]: prisms.

**Bromo-p-nitro-phenol**  $C_6H_4Br(NO_2)(OH)$  [13:56]. [102°]. Formed by brominating p-nitro-phenol (Brunck, Z. 1867, 204). Satiny needles (from ether or alcohol); m. sol. water.—Ba( $C_6H_3BrNO_2$ )<sub>2</sub> 6aq: orange needles, m. sol. water.

**Methyl ether** MeA'. [106°]. From the potassium salt, MeI and MeOH at 110°. White needles (from alcohol). V. sol. hot alcohol or ether, m. sol. hot water (Staedel, A. 217, 66).

**Ethyl ether** EtA'. [98°] (S.); [55°] (H.). Formed like the preceding (S.). From p-nitro-phenetol and Br (Hallock, B. 14, 37). Yellow needles (from alcohol). V. sol. alcohol or ether.

**Benzylether**  $C_6H_4Br(NO_2)(OC_2H_5)$ . [126°]. Nearly colourless plates (from alcohol). Insol. water, sol. alcohol and ether (R. a. H.). Reduced by Sn and HCl to bromo-p-amido phenol and  $C_2H_5Cl$ .

**Bromo-di-nitro-phenol**  $C_6H_2Br(NO_2)_2(OH)$  [13:54]. [86°] (K.); [71°] (Austen); [76°] (Armstrong). Formed by nitrating p-bromo-phenol in HOAc, or by brominating and nitrating o-nitro-phenol (Körner, A. 137, 205; Armstrong a. Prevost, B. 7, 922). Formed also by brominating di-nitro-phenol [64°] (Körner, G. 4, 805); and by boiling di-nitrated p-di-bromo-benzene with aqueous  $KNO_3$  (Austen, Am. S. [3] 16, 46). Yellow monoclinic prisms,  $abc: 2.795:1.1:778$ ;  $\beta = 67^\circ 53'$  (Arzruni, loc. cit.). Water and Br at 100° change it into the isomeride [118°] (Armstrong, C. J. 28, 520).  $HNO_3$  forms picric acid.

**Salts**.—NH<sub>4</sub>A': silky red needles; sol. boiling water and alcohol.—NH<sub>4</sub>A' aq.—BaA'<sub>2</sub>: yellow needles, sol. hot water.—CuA'<sub>2</sub>: short brown needles, insol. water.—KA': long red needles, sl. sol. water.—AgA'.—CaA'<sub>2</sub> 8aq.

**Ethylether** EtA' [66°]: small needles, sol. alcohol and hot water; saponified by cold

NaOHAq (Schoonmaker a. Van Mater, Am. S. 187).

**Bromo-di-nitro-phenol**  $C_6H_2Br(NO_2)_2(OH)$ . [91-5°]. Formed by nitrating m-bromo-phenol, and also from di-bromo-di-nitro-phenol [117°] and boiling aqueous KOH (Körner, G. 4, 305). Prisms (from alcohol or ether). The K salt forms yellow needles.

**Methyl ether** MeA' [109°].

**Bromo-di-nitro-phenol**  $C_6H_2Br(NO_2)_2OH$  [13:55:6]. [118°].

**Formation**.—1. From (1,3,4)-di-nitro phenol and Br (Laurent, Rev. Scient. 6, 65).—2. By nitrating o-bromo-phenol (Körner, G. 4, 394).—3. From o-nitro-phenol, by bromination and nitration.—4. By boiling bromo-di-nitro-aniline [144°] with aqueous KOH (Körner).—5. By nitrating brominated phenol disulphonic acid or di-brominated phenol p-sulphonic acid (Armstrong a. Brown, C. J. 25, 861, 865).—6. By warming the isomeride [c. 76°] with Br and water (Armstrong, C. J. 28, 520).—7. From picric acid, water, and Br (Armstrong, B. 6, 650).—8. By nitrating tri-bromo-phenol (Armstrong a. Harrow, C. J. 29, 477).—9. From bromo-nitro-benzyl-phenol in HOAc by  $HNO_3$ ; benzyl being displaced by  $NO_2$  (Reunie, C. J. 41, 225).

**Properties**.—Yellow prisms. Needles (from alcohol).

**Salts**.—KA' aq: flat yellow needles, sl. sol. cold water.—KA' 1½aq.—BaA'<sub>2</sub> 3½aq.—BaA'<sub>2</sub> 4aq.—BaA'<sub>2</sub> 5aq: yellow needles, sl. sol. water.—CaA'<sub>2</sub> 7aq.—CaA'<sub>2</sub> 8aq.—CaA'<sub>2</sub> 12aq.—NH<sub>4</sub>A' 2aq.—NaA' 1½aq.—PbA'<sub>2</sub> 2aq.

**Methyl ether** MeA'. [48°]. From bromo-anisic acid and  $HNO_3$ . Yellow prisms, sol. alcohol and ether, insol. water (Balbiano, G. 14, 235).

**Di-bromo-o-nitro-phenol**  $C_6H_2Br_2(NO_2)(OH)$  [13:55:6]. [117-5°].

**Formation**.—1. From o-nitro-phenol and Br (Brunck, Z. 1867, 203; Körner).—2. From (1,3,4)-di-bromo-phenol by nitration (K.).—3. By nitrating di-bromo-phenol sulphonic acid (Armstrong a. Brown, C. J. 25, 863).

**Properties**.—Golden monoclinic prisms (from alcohol);  $abc: 515:1:591$ ;  $\beta = 65^\circ 23'$  (Arzruni, Z. Kryst. 1, 436). Volatile with steam; may be sublimed; v. sl. sol. water. Heated with bromine at 100° it gives some of the isomeride [141°] together with t. tra-bromo-quinone and (1,3,6)-bromo-nitro-phenol (Ling, C. J. 51, 147).

**Salt**.—KA': scarlet needles, v. sl. sol. cold water.

**Methyl ether** MeA'. [77°]. From the silver salt and MeI; alcohol & NH<sub>3</sub> converts it into di-bromo-nitro-aniline [127°] whence  $HNO_3$  gives di-bromo-nitro-benzene [105°] (K.).

**Ethylether** EtA'. [46°]. From the silver salt, EtI and alcohol at 100° (Staedel, A. 217, 58). V. sol. benzene, alcohol or ether, insol. water.

**Benzylether**  $C_6H_2Br_2(NO_2)(OC_2H_5)$ . [65°]. Yellow crystals (from ether). Sol. benzene, chloroform, and glacial acetic acid, insol. water (R. a. H., J. pr. [2] 32, 57). Reduced by Sn and HCl to di-bromo-amido-phenol and benzyl chloride.

**Di-bromo-m-nitro-phenol**  $C_6H_2Br_2(NO_2)(OH)$ . [91°]. Formed by heating m-nitro-phenol (1

(mol.) with bromine (2 mols.). Yellowish plates. V. sol. alcohol, sl. sol. water.

**Salts.**—KA': easily soluble orange-red needles.—AgA': sparingly soluble red powder.—BaA', 6aq: very soluble red needles.

**Ethyl ether**  $C_6H_4Br(NO_2)OEt$ : [110°]: yellowish needles, sol. hot alcohol (Lindner, B. 18, 613).

**Di-bromo-*p*-nitro-phenol**  $C_6H_2Br_2(NO_2)(OH)$  [1:5:3:6]. [142°] (Lellmann a. Grothmann, B. 17, 2731).

**Formation.**—1. By brominating *p*-nitro-phenol or its sulphonic acid (Brunck, Z. 1867, 204; Post a. Brackebusch, A. 205, 94).—2. By nitrating tri-bromo-phenol dissolved in HOAc (Armstrong a. Harrow, loc. cit.).—3. In small quantity by heating the isomeric [117°] with Br (Ling, C. J. 51, 147).

**Properties.**—Prisms, sl. sol. water, v. sol. alcohol and ether.

**Salt.**—BaA', 10aq: yellow needles, effervescing to a red powder.—BaA', 31aq.—AgA'.

**Methyl ether** MeA': [123°] (Körner, G. 4, 390). From di-bromo-anisic acid and  $HNO_3$ , the  $CO_2H$  being displaced by  $NO_2$  (Balbiano, G. 14, 9). Pyramidal needles; converted by  $NH_3$  into di-bromo-*p*-nitro-aniline [203°].

**Ethyl ether** [108°]. Long quadratic columns (Stadel, A. 217, 67).

**Benzyl ether**  $C_6H_2Br_2(NO_2)(OC_6H_5)$ . [94°]. Nearly colourless needles (from alcohol). Insol. water, sl. sol. alcohol, ether, benzene, chloroform, and glacial acetic acid (R. a. H.). Reduced by Sn and HCl to di-bromo-*p*-amido-phenol (*q. v.*) and benzyl chloride.

**Tri-bromo-nitro-phenol**  $C_6HBr_3(NO_2)OH$  [6:4:2:3:1]. [85°] (L.); [89°] (D.). Formed by heating *m*-nitro-phenol with Br (3 mols.) at 100° (Lindner, B. 18, 614). Colourless crystalline powder; v. sol. alcohol, ether, and benzene, v. sl. sol. hot water.

**Salts.**—ANH<sub>4</sub>: sparingly soluble microscopic needles.—AKaq: v. sol. water.—A<sub>2</sub>Br 8aq: sparingly soluble orange-yellow crystals.—A<sub>2</sub>Br 6aq.—A<sub>2</sub>Mg: easily soluble red plates.

***o*-Nitro-benzoyl derivative**

$C_6HBr_2(NO_2)O.CO.C_6H_4(NO_2)$ : [129° cor.]; very small colourless needles.

***m*-Nitro-benzoyl derivative**

$C_6HBr_2(NO_2)O.CO.C_6H_3(NO_2)$ : [154° cor.]; glistering colourless needles; S. (90 p.c. alcohol) 253 at 14° (Dacomo, B. 18, 1167).

**Ethyl ether** EtA': [79°]; prisms.

#### BROMO-NITRO-PHENOL SULPHONIC ACID

$C_6H_4BrNSO_3$ , i.e.  $C_6H_4Br(NO_2)(OH)SO_3H$  [1:3:6:5]. Formed, together with di-bromo-nitro-phenol, by brominating (1, 4, 3)-nitro-phenol sulphonic acid (Post a. Brackebusch, A. 205, 92).—CaA', 3aq.—BaA', 3aq.— $C_6H_4BrNSO_3(PbOH)$ , 21aq.

**Bromo-phenol sulphonic acids** have been obtained by Armstrong (C. J. 25, 857; B. 7, 404, 924) and Post (B. 7, 169) by the action of nitric acid on various brominated phenol sulphonic acids, and by the action of bromine on (1, 2, 5)-nitro-phenol sulphonic acid.

**BROMO-NITRO-DIPHENYL**  $C_{12}H_7BrNO_2$ , i.e. [4:1]  $C_6H_4Br.C_6H_4(NO_2)$  [1:4]. [173°] (above 360°). Formed by heating diphenyl (1 pt.) with conc.  $HNO_3$  (1 pt.), or from amido-nitro-diphenyl by the diazo-reaction (Schultz, A. 174, 218). Long white needles (from toluene).  $CrO_3$  gives

*p*-bromo-benzoic acid and a little *p*-nitro-benzoic acid.

**Bromo-nitro-diphenyl**  $C_{12}H_7BrNO_2$ , i.e.

[4:1]  $C_6H_4Br.C_6H_4(NO_2)$  [1:2]. [65°]. (c. 360°). Formed together with the preceding. Monoclinic columns.  $CrO_3$  gives *p*-bromo-benzoic acid (Schultz, A. 207, 548).

**Di-bromo-nitro-diphenyl**

$C_{12}H_6Br_2C_6H_4(NO_2)$ . [127°]. Formed by nitration of di-bromo-diphenyl in acetic acid solution (Lellmann, B. 15, 2837). Yellowish crystals; v. sol. alcohol, benzene, and acetic acid.

**Di-bromo-di-nitro-diphenyl**  $C_{12}H_4Br_2(NO_2)_2$ .

From *pp*-di-bromo-diphenyl and fuming  $HNO_3$  (Fittig, A. 132, 206; S.). Hair-like crystals (from benzene). Sn and HCl give di-bromo-di-amido-diphenyl [89°].

**Di-bromo-tri-nitro-diphenyl**

$C_{12}H_3Br_3(NO_2)_3$ .  $C_{12}H_3Br_3(NO_2)_3$ . [177°]. Formed by nitration of di-bromo-diphenyl with cold fuming  $HNO_3$  (1:55) (Lellmann, B. 15, 2838). Small colourless needles. Sol. benzene, sl. sol. alcohol.

#### BROMO-NITRO-PHENYL ACETIC ACID

$C_6H_4Br(NO_2)CH_2.CO_2H$  [1:2:4]. [114°]. Formed by nitration of a mixture of *o*- and *p*-bromo-phenyl-acetic acids (Bedson, C. J. 37, 97). Flat greenish-yellow needles. Sol. hot, insol. cold water. V. sol. alcohol and ether.  $K_2Cr_2O_7$  and  $H_2SO_4$  give  $C_6H_4Br(NO_2)CO_2H$  [199°].

**Salts.**—BaA', aq. Its aqueous solution gives white pps. with  $AgNO_3$ ,  $Pb(OAc)_2$ , and a blue pp. with  $Cu(OAc)_2$ .

**Methyl ether.** MeA'. [41°]. Needles.

**Ethyl ether.** Oil.

(a)-Bromo-nitro-phenyl-acetic acid

$C_6H_4Br(NO_2)CH_2.CO_2H$ . [169°]. Formed by nitration of mixture of *o*- and *p*-bromo-phenyl-acetic acids (Bedson). Yellowish-white, branching needles. V. sol. alcohol and ether, insol. cold, sol. hot water.

**Salt.**—BaA', 1aq. Its aqueous solution gives white pps. with  $AgNO_3$  and  $Pb(OAc)_2$ , but a green pp. with  $Cu(OAc)_2$ .

**Methyl ether** [68°]. Flat needles.

**Ethyl ether.** Yellowish needles.

(β)-Bromo-nitro-phenyl-acetic acid

$C_6H_4Br(NO_2)CH_2.CO_2H$ . [162°]. Formed together with the two preceding (Bedson). Small yellow prisms.

#### BROMO-DI-NITRO-DI-PHENYL-AMINE

$C_{12}H_8BrN_2O_2$ , i.e.  $C_6H_4Br(NO_2)_2.NH.C_6H_5$ . **Bromo-nitro-phenyl-amine**. [120°]. Formed by warming bromo-di-nitro-benzene [100°] with aniline (Austen, D. 9, 920). Orange hair-like needles (from alcohol).

**Bromo-di-nitro-di-phenyl-amine**

$C_{12}H_8Br.NH.C_6H_4(NO_2)_2$ . **Bromo-phenyl-di-nitro-phenyl-amine**. [153°]. From (1, 2, 4)-bromo-di-nitro-benzene and di-*p*-bromo-di-phenyl-urea at 170°. Yellow needles (from ether) (Willgerodt, B. 11, 60°).

**Bromo-tri-nitro-di-phenyl-amine**

$C_{12}H_7Br(NO_2)_3.NH.C_6H_4(NO_2)$ . [158°]. From bromo-di-nitro-di-phenyl-amine [120°] and  $HNO_3$  (A.).

**Di-bromo-di-nitro-di-phenyl-amine**

$C_{12}H_7Br_2(NO_2)_2.N$ . [196°]. Formed by bromination of di-nitro-di-phenyl-amine (Leymann, B. 15, 1236).

**Di-bromo-tetra-nitro-di-phenyl-amine**

$C_6H_4Br(NO_2)_2.NH.C_6H_4Br(NO_2)_2$ . [235°–242°].

From  $\text{NMe}(\text{C}_6\text{H}_4\text{Br})_2(\text{C}_6\text{H}_4\text{Br})$  and  $\text{HNO}_3$  (Gnehm, B. 8, 929). Laminas (from HOAc).

**Tri-bromo-di-nitro-di-phenyl-amine**

$\text{C}_{12}\text{H}_5\text{Br}_3(\text{NO}_2)_2\text{N}$ . [210°]. Formed by nitrating tetra-bromo-di-phenyl-amine ( $\text{C}_6\text{H}_4\text{Br}_2)_2\text{NH}$  (Gnehm a. Wyss, B. 10, 1323).

**BROMO-NITRO-PHENYL BENZYL OXIDE**

**v. Bromo-nitro-phenol, Benzyl ether.**

**DI-BROMO-NITRO-PHENYL-CARBAMIC**

**ACID. Methyl ether**

[1:3:4]  $\text{C}_6\text{H}_3\text{Br}_2(\text{NO}_2)\text{NHCO}_2\text{Me}$ . [152°]. From methyl-(1,3,4)-di-bromo-phenyl-carbamate and  $\text{HNO}_3$  (Hentschel, J. pr. [2] 34, 425). Prisms (from alcohol).  $\text{NH}_3$  forms (1,3,4)-di-bromo-aniline.

**BROMO-NITRO-m-PHENYLENE-DIAMINE**

$\text{C}_6\text{H}_3\text{BrN}_2\text{O}_2$  i.e.  $\text{C}_6\text{H}_3\text{Br}(\text{NO}_2)(\text{NH}_2)_2$  [1:2:3:5]. From tri-bromo-nitro-benzene and alcoholic  $\text{NH}_3$ , for some days at 175° (Körner, G. 4). Orange needles; decomposes at 163°. Converted into *p*-bromo-benzene by the diazo-reaction.

**Bromo-nitro-p-phenylene-diamine**

$\text{C}_6\text{H}_3\text{Br}(\text{NO}_2)(\text{NH}_2)_2$  [1:4:2:5]. [156°]. From tri-bromo-nitro-benzene [94°] and alcoholic  $\text{NH}_3$  at 110° (Körner, G. 4). Pyramidal needles. Converted by diazo-reaction into *p*-bromo-benzene.

**BROMO-NITRO-PHENYL-ETHANE v.**

**BROMO-NITRO-PHENYL-BENZENE.**

**Di-bromo-di-nitro-s-di-phenyl-ethane**

$\text{C}_8\text{H}_4(\text{NO}_2)_2\text{CHBrCHBrC}_6\text{H}_4\text{NO}_2$ . [above 300°]. *Di-bromide of di-p-nitro-stilbene*. Split up by heat into 2HBr and di-nitro-tolane (Elbs a. Bauer, J. pr. [2] 31, 315).

**Di-bromo-di-nitro-s-di-phenyl-ethane**

$\text{C}_{12}\text{H}_8\text{Br}_2(\text{NO}_2)_4$ . *Di-bromo-di-nitro-di-benzyl*. [205°]. Formed by nitrating di-*p*-bromo-di-benzyl (Fittig a. Stelling, A. 137, 260). Sword-shaped crystals (from benzene).

**BROMO-NITRO-PHENYL ETHYL OXIDE v.**

**Ethyl-Bromo-nitro-phenol.**

**aa-DI-BROMO-aa-DI-NITRO-ω-PHENYL-**

**METHYL-CARBINOL.**

*Ethyl ether*  $\text{CBr}_2(\text{NO}_2)\text{CH}(\text{C}_6\text{H}_4\text{NO}_2)\text{OEt}$ .

[99°].—1. From the compound of alcohol with *am*-di-nitro-cinnamic ether (*q. v.*) by simultaneous treatment with aqueous NaOH and Br (Friedländer a. Lazarus, A. 229, 237).—2. From *ω*-*m*-di-nitro-styrene, alcohol, aqueous NaOH and Br. White plates (from dilute alcohol). Insoluble in aqueous NaOH.

*Methyl ether*  $\text{CBr}_2(\text{NO}_2)\text{CH}(\text{C}_6\text{H}_4\text{NO}_2)\text{OMe}$ . [140°]. Formed in a similar way from the compound of methyl alcohol with the same body, or from *ω*-*m*-di-nitro-styrene, methyl alcohol, Br<sub>2</sub> and aqueous NaOH. White plates.

**BROMO-NITRO-PHENYL-METHYL-**

**KETONE v. Bromo-nitro-acetophenone.**

**p-BROMO-o-NITRO-β-PHENYL-PROPIONIC**

**ACID**  $\text{C}_9\text{H}_7(\text{Br})(\text{NO}_2)\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [4:2:1]. *Bromo-nitro-hydrocinnamic acid*. [112°]. Prepared by the action of HBr on the diazo-compound from *p*-amido-o-nitro-hydrocinnamic acid. Formed together with the (4,3,1)-isomeride by nitration of *p*-bromo-hydrocinnamic acid. Flat feathery crystals. By reduction with tin and HCl it gives *p*-bromo-hydrocarbostyryl (Gabriel a. Zimmermann, B. 13, 1682).

**p-Bromo-m-nitro-β-phenyl-propionic acid**

$\text{C}_9\text{H}_7(\text{Br})(\text{NO}_2)\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [4:3:1]. [90°–95°]. Long glistening needles. Prepared as above. On reduction with tin and HCl it gives *p*-bromo-

*m*-amido-hydrocinnamic acid (Gabriel a. Zimmermann, B. 13, 1683).

**β-Bromo-o-nitro-β-phenyl-propionic acid**

$\text{C}_9\text{H}_7(\text{NO}_2)\text{CHBrCH}_2\text{CO}_2\text{H}$ . [140°]. From *o*-nitro-cinnamic acid, HOAc, and HBr at 100° (Einhorn, B. 16, 2208). Monoclinic crystals; v. sol. ordinary solvents, sl. sol. benzene.

*Reactions*.—1. Boiling water forms indoyl. 2. NaOH aq forms nitro-cinnamic acid.—3. Cold  $\text{Na}_2\text{CO}_3$  aq forms the lactone of *o*-nitro-β-oxy-phenyl-propionic acid.—4. Hot  $\text{Na}_2\text{CO}_3$  aq gives nitro-cinnamic acid, nitro-oxy-phenyl-propionic acid, and *o*-nitro-styrene.

**β-Bromo-m-nitro-β-phenyl-propionic acid**

$\text{C}_9\text{H}_7(\text{NO}_2)\text{CHBrCH}_2\text{CO}_2\text{H}$ . [96°]. Prepared by heating an acetic acid solution of *m*-nitro-cinnamic acid with HBr at 100°. V. sol. alcohol, sl. sol. toluene, insol. petroleum-ether.

*Reactions*.—1. By boiling with water it chiefly gives *m*-nitro-styrene.—2. An excess of alkali converts it back into *m*-nitro-cinnamic acid.—3. By adding the powdered acid to an aqueous solution of  $\frac{1}{2}$  mol. of  $\text{Na}_2\text{CO}_3$ , it yields 30 p.c. of *m*-nitro-styrene, 20 p.c. of *m*-nitro-cinnamic acid, and 10 p.c. of *m*-nitro-β-oxy-β-phenyl-propionic acid. If the powdered acid is added to a cold solution of  $\text{Na}_2\text{CO}_3$ , the β-lactone is formed (Frausnitz, B. 17, 595).

**β-Bromo-p-nitro-phenyl-propionic acid**

$\text{C}_9\text{H}_7(\text{NO}_2)\text{CHBrCH}_2\text{CO}_2\text{H}$ . [172°]. Prepared by heating *p*-nitro-cinnamic ether with HBr at 100°. Prisms; sol. hot alcohol, sl. sol. water and benzene.

*Reactions*.—1. Long boiling with dilute  $\text{H}_2\text{SO}_4$  (25 p.c.) reconverts it into *p*-nitro-cinnamic acid.—2. Heated with water it yields *p*-nitro-β-oxy-phenyl-propionic acid (72 p.c.) and *p*-nitro-styrene (28 p.c.).—3. Cold aqueous KOH gives *p*-nitro-oxy-phenyl-propionic acid and its lactone. Alcoholic KOH yields almost entirely *p*-nitro-cinnamic acid.—4. Aqueous  $\text{NH}_3$  yields the lactone which by excess of  $\text{NH}_3$  is converted into the corresponding amido-acid.

*Ethyl ether* EtA'. [81°]; colourless plates (Basler, B. 16, 3001).

**Di-bromo-o-nitro-phenyl-propionic acid**

$\text{C}_9\text{H}_5(\text{NO}_2)\text{CHBrCHBrCO}_2\text{H}$ . *Dibromide of o-nitro-cinnamic acid*. [c. 180°]. From Br and *o*-nitro-cinnamic acid (Baeyer, B. 13, 2257). Needles or plates; sol. hot water. NaOH aq gives *o*-nitro-phenyl-propionic acid. Zinc-dust and NaOH give indol.

*Methyl ether* MeA'. [99°].

*Ethyl ether* EtA'. [71° uncor.] (M.)

From *o*-nitro-cinnamic ether and Br (Müller, A. 212, 130). Alcoholic KOH converts it into *o*-nitro-phenyl-propionic acid. Heated with water at 120° it gives *o*-nitro-cinnamic acid.

**Di-bromo-p-nitro-phenyl-propionic acid**

$\text{C}_9\text{H}_5(\text{NO}_2)\text{CHBrCHBrCO}_2\text{H}$ . [218°]. From *p*-nitro-cinnamic acid and Br (Drewson, A. 212, 151). Rhombic prisms (from glacial HOAc). M. sol. water or glacial HOAc, v. sol. alcohol or ether, sl. sol. benzene, v. sl. sol. benzoline. Aqueous NaOH forms *p*-nitro-cinnamic and *p*-nitro-phenyl-propionic acids.—CaA'.

*Ethyl ether* EtA'. [111°]. From *p*-nitro-cinnamic ether and Br in  $\text{CS}_2$  (C. L. Müller, A. 212, 129). Columns (from  $\text{CS}_2$ ); v. sol. hot alcohol, ether, or benzoline. Alcoholic KOH converts it into a mixture of two isomeric bromo-  
q q 2

nitro-cinnamic ethers, and *p*-nitro-phenyl-propionic acid. Heated with water at 120° it gives *p*-nitro-cinnamic acid.

#### BROMO-NITRO-PHTHALIC ACID

$C_6H_3Br(NO_2)(CO_2H)_2$  [1:4:2:3]. From di-bromonaphthalene (82°) and  $HNO_3$ .— $Na_2A''$  (Guarachi, *A.* 222, 277).

#### $\alpha$ -BROMO- $\omega$ -NITRO-PROPANE

$CH_3CH_2CH_2Br(NO_2)$ . (c. 160°). Formed together with di-bromo-nitro-propane by the action of potash and Br on nitro-propane (V. Meyer a. Tscherniak, *A.* 180, 116). Oil, sol. potash.

$\alpha$ -Bromo- $\alpha$ -nitro-propane  $CH_3.CBr(NO_2).CH_3$ . (150°). From  $CH_3CH_2(NO_2).CH_3$ . Insol. potash.

Di-bromo-nitro-propane  $CH_3CH_2CBr_2(NO_2)$ . (181°-186°). From bromo-nitro-propane, Br, and potash. An oil, insol. potash.

#### TRI-BROMO DI-NITRO-PROPIONIC ACID

$C_6H_2Br_3N_2O_6$  i.e.  $CBr_2C(NO_2)_2.CO_2H$ . From tribromo-phloroglucin and conc.  $HNO_3$  (Benedikt, *A.* 184, 255). Silky scales, insol. cold water, v. e. sol. alcohol and ether; decomposed by boiling water.

BROMO-NITRO-PROPYL-BENZENE *v.* BROMO-NITRO-CUMENE.

#### BROMO-NITRO-PROPYL-PHENOL *v.* BROMO-CUMENOL

#### DI-BROMO-DI-NITRO-PYRROL

$C_4H_2Br_2N_2O_4$  i.e.  $\begin{matrix} CBr_2C(NO_2) \\ | \\ CBr_2C(NO_2) \end{matrix} NH$ . [169°].

Formed by dissolving di-bromo-nitro-pyrrol methyl ketone [206°] in a mixture of fuming  $HNO_3$  and conc.  $H_2SO_4$  at -18°, and precipitating in water. Silky scallots (containing aq). At the ordinary temperature it is converted into di-bromo-maleimide (Ciamiceian a. Silber, *B.* 20, 699; *A.* 17, 262).

#### DI-BROMO-NITRO-PYRRYL METHYL KETONE

$\begin{matrix} CBr_2C(NO_2) \\ | \\ >NH \\ | \\ CBr_2C-CO.CH_3 \end{matrix}$ . [206°]. Long needles. Formed by the action of cold nitric acid upon di-bromo-pyrrolylene-di-methyl-di-ketone  $CBr_2C-CO.CH_3$ , [171°], which is formed by passing bromine-vapour into pyrrolylene-di-methyl-di-ketone (Ciamiceian a. Silber, *B.* 20, 699).

#### Di-bromo-nitro-pyrryl methyl ketone

$CBr : CBr$   
 $\begin{matrix} | \\ >NH \\ | \\ C(NO_2)_2C-CO.CH_3 \end{matrix}$ . [176°]. From nitro-pyrryl methyl ketone [197°] and Br. Needles.

BROMO-NITRO-QUINOLINE  $C_8H_5N(Br)(NO_2)$  [133°]. Formed by nitration of bromo-quinoline. Long glistening needles. Volatile undecomposed. Sol. alcohol and ether, sl. sol. water. Weak base.  $-Br_2H.Cl.PtCl_4$ ; short orange-yellow prisms (La Coste, *A.* 15, 1918).

#### DI-BROMO-NITRO-QUINONE

$C_6H_2Br_2(NO_2)_2O_2$  [6:2:3:4:1]. [246°]. Yellow plates; v. sl. sol. hot water and cold alcohol. Formed by the action of a mixture of  $HNO_3$  and  $H_2SO_4$  upon the propionyl derivative of tri-bromophenol (Guarachi a. Dacomo, *B.* 18, 1174).

#### BROMO-NITRO-RESORCIN Ethyl ether

$C_6H_3Br(NO_2)(OH)(OEt)$ . [114°]. From ethyl (1, 2, 4)-nitro-resorcin and Br (Weselsky, *M.* 1, 898).

Di-bromo-nitro-resorcin  $C_6H_3Br_2NO_4$  i.e.  $C_6H_2Br_2(NO_2)(OH)_2$ . [147°]. From (1, 2, 4)-nitro-resorcin [115°] in ether and Br (Weselsky, *A.* 164, 7). Golden laminae.— $Ba(C_2H_5Br_2NO_4)_2$  4aq.

Ethyl ether  $C_6H_3Br_2(NO_2)(OEt)(OH)$  [1:5:3:2:6]. [69°]. From ethyl nitro-resorcin and Br (W.).

Di-bromo-nitro-resorcin  $C_6H_2Br_2(NO_2)(OH)_2$  [1:3:5:4:6]. [117°]. From (1, 2, 6)-nitro-resorcin and Br (W.).

Bromo-di-nitro-resorcin  $C_6H_3Br(NO_2)_2(OH)_2$ . [193°]. Formed by nitrating di-bromo-nitro-resorcin or by brominating di-nitro-resorcin (Fèvre, *Bil.* [2] 39, 590; *C. R.* 96, 790; Typke, *B.* 16, 555). Orange needles; sl. sol. boiling alcohol.  $-K_2A''$  1 aq.; red needles.— $Na_2A''$  2 aq.— $BaA''$  3 aq.— $(NH_4)_2A''$  aq.

Acetyl derivative: [135°]; prisms.

BROMO-NITRO-SALICYLIC ACID *v.* BROMO-NITRO-OXY-BENZOIC ACID.

#### DI-BROMO-NITROSO-RESORCIN

$C_6H_2Br_2(NO)(OH)_2$ . From nitroso-resorcin and Br (Fèvre, *Bil.* [2] 39, 591). Yellowish needles (containing 2 aq) which turn brown at 138° and decompose at 150°; insol. benzene, sl. sol. cold water, v. e. sol. alcohol.

#### BROMO-NITROSO-THYMOL

$C_8H_8MePrBr(NO)(OH)$ . [c. 135°]. From nitroso-thymene and Br (Mazzara a. Desalzo, *G.* 16, 196).

#### BROMO-NITRO-STYRENE Ph.CBr:CHNO<sub>2</sub>

[68°]. From di-bromo-nitro-phenyl-ethane  $PhCBr_2H.CHBrNO_2$  and aqueous  $NaOH$  (Priests, *A.* 225, 313). Golden needles or plates (from light petroleum). Smells something like hay; when freshly prep. from alcoholic solution by water it is soluble in alkalis, hence its constitution is as above, rather than  $Ph.CH:CBr(NO_2)$ .

#### DI-BROMO-DI-NITRO-THIOPHENE

$C_4SBr_2(NO_2)_2$ . [134°]. Light-yellow crystals. V. sol. hot alcohol. Formed by nitration of di- or tri-bromo-thiophene (Kveis, *B.* 17, 2074; Rosenberg, *B.* 18, 3029).

#### TRI-BROMO-NITRO-THIOPHENE

$C_4SBr_3(NO_2)$ . [106°]. Formed by nitration of tri-bromo-thiophene. Felted yellow needles. V. sol. ether, sl. sol. alcohol (Rosenberg, *B.* 18, 3028).

#### BROMO-NITRO-THYMOL

$C_8H_8MePrBr(NO_2)(OH)$ . [101°]. From bromo-nitroso-thymol and  $K_2FeCy_4$  (Mazzara, *G.* 16, 196).

#### BROMO-NITRO-TOLUENE

$C_6H_4Me(NO_2)Br$  [1:2:3]. Oil. From bromo-nitro-*m*-toluidine by nitrous gas and alcohol (Neville a. Winther, *C. J.* 37, 630).

Bromo-nitro-toluene  $C_6H_4Me(NO_2)Br$  [1:3:4]. [32°]. (256°). S.G.  $d_4^{20}$  1.631. From the corresponding nitro-toluidine by the diazo-perbromide reaction (Neville a. Winther, *C. J.* 37, 442). Formed also by nitrating *p*-bromo-toluene (Wroblewsky, *A.* 168, 176) and by treating *m*-nitro-toluene with Br and  $FeBr_2$  at 70° (Scheufelen, *A.* 231, 180).

Bromo-nitro-toluene  $C_6H_4Me(NO_2)Br$  [1:2:4]. [45°]. (257°). From the corresponding nitro-toluidine [78°] by the diazo-perbromide reaction (Beilstein a. Kuhlberg, *A.* 158, 340; Neville a. Winther, *C. J.* 37, 441). Formed also, together with the preceding, by nitrating *p*-bromo-toluene (W.). Large monoclinic tables.

Bromo-nitro-toluene  $C_6H_4Me(NO_2)Br$  [1:2 or 6:3]. [55°]. (267°). Formed by nitrating *m*-bromo-toluene (W.; Grete, *A.* 177, 246).

Trimetric crystals; on reduction it gives bromo-*o*-toluidine.

**Bromo-nitro-toluene**  $C_6H_4Me(NO_2)Br$  [1:4:2]. [77°]. From  $C_6H_4(CH_3)Br(NO_2)(NH_2)$  [1:2:4:5] (Neville a. Winther, *C. J.* 39, 85). From *p*-nitro-toluene,  $FeBr_3$ , and bromine (Scheufelen, *A.* 231, 171). Also from diazo-nitro-toluene piperidide  $C_6H_4Me(NO_2)N_2NC_6H_5$  and boiling  $HBrAq$  (Wallach, *A.* 235, 218). Needles.

**Bromo-nitro-toluene**  $C_6H_4Me(NO_2)Br$  [1:3:6]. [78°]. From *m*-nitro-toluene,  $FeBr_3$ , and bromine (Scheufelen, *A.* 231, 179). From (3, 1, 6)-nitro-*o*-toluidine (N. a. W.).

**Bromo-nitro-toluene**  $C_6H_4Me(NO_2)Br$  [1:3:5]. [81°]. (N. a. W.); [86°] (W.); [270°]. Formed (a) from bromo-nitro-*p*-toluidine [65°], (b) from nitro-(5, 1, 2)-bromo-*o*-toluidine [143°], or (c) from bromo-nitro-*o*-toluidine [181°] by the usual methods (Neville a. Winther, *C. J.* 37, 431; Wroblewsky, *A.* 192, 203). Hence it can be prepared from a mixture of acetyl-*o*- and *p*-toluidines by successive bromination, nitration, saponification, and diazotisation.

**Bromo-di-nitro-toluene**  $C_6H_2Me(NO_2)_2Br$ . [104°]. From *m*-bromo-toluene and fuming  $HNO_3$  (Grete, *A.* 177, 258).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:4:6:2:3]. [c. 57°]. From  $C_6H_4(CH_3)Br_2$  [28°] by nitration (Neville a. Winther, *C. J.* 37, 434).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:4:2:6]. [58°]. From  $C_6H_4(CH_3)(NH_2)(NO_2)Br_2$  [124°–130°] by ethyl nitrite (Neville a. Winther, *C. J.* 37, 445). Also from (2, 4, 1)-bromo-nitro-toluene,  $FeBr_3$ , and  $Br$  (Scheufelen, *A.* 231, 178).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:5:3:4]. [63°]. From bromo-nitro-toluidine,  $C_6H_4(CH_3)(NO_2)(NH_2)Br$  [1:5:4:3] by diazo-perbromide reaction (Neville a. Winther, *C. J.* 37, 417). Colourless plates (from alcohol).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:3:2:5]. [70°]. From bromo-nitro-*o*-toluidine, [143°], by diazo-perbromide reaction (Neville a. Winther, *C. J.* 37, 448).

**Di-bromo-nitro-toluene**  $C_6H_2MeBr_2(NO_2)_2$  [1:4:6:2:2]. [80°]. By nitrating di-bromo-toluene from di-bromo-*m*-toluidine, [75°] (Neville a. Winther, *C. J.* 37, 441).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:6:3:4]. [87°]. Formed by nitrating the corresponding di-bromo-toluene. Converted by reduction and diazo-reaction into (2, 4, 5, 1)-tri-bromo-toluene [113°] (Neville a. Winther, *C. J.* 39, 83).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:4:2:5]. [88°]. From  $C_6H_4(CH_3)(NO_2)(NH_2)Br_2$  [181°] by the diazo-perbromide reaction. Formed also by nitrating  $C_6H_4(CH_3)Br_2$  [1:2:5]. Converted by reduction and diazotisation into (2, 4, 5, 1)-tri-bromo-toluene [113°] (Neville a. Winther, *C. J.* 37, 445; 39, 83).

**Di-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:3:5:6]. [106°]. From bromo-nitro-*o*-toluidine, [181°], by exchange of  $NH_2$  for  $Br$  (Neville a. Winther, *C. J.* 37, 433).

**$\omega$ -Di-bromo-nitro-toluene**  $C_6H_3CBBr_2(NO_2)_2$ . **Phenyl-di-bromo-nitro-methane**. Colourless oil. Formed by the action of bromine upon an aqueous solution of the di-sodium salt of nitro-benzylidene-phthalide

$C_6H_4 \begin{matrix} \diagup C(ONa) \diagdown \\ \diagdown CO \diagup \end{matrix} \begin{matrix} \diagup CN(NO_2) \diagdown \\ \diagdown O \diagup \end{matrix} \begin{matrix} \diagup H \diagdown \\ \diagdown \end{matrix}$ . Volatile with steam (Gabriel a. Koppe, *B.* 19, 1145).

**Di-bromo-di-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$ . [158°]. Formed by nitrating  $C_6H_4(CH_3)Br_2$  [39°] (Neville a. Winther, *C. J.* 37, 437).

**Di-bromo-di-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$ . [105°]. Formed at the same time as the preceding (N. a. W.).

**Di-bromo-di-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_2$  [1:2:2:2:6]. [161°]. By nitration of (2, 6, 1)-di-bromo-toluene (N. a. W.).

**Tri-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_3$  [1:4:2:5:6]. [106°]. From di-bromo-nitro-*m*-toluidine, [125°–130°], by the diazo-perbromide reaction. White needles (Neville a. Winther, *C. J.* 39, 85°).

**Tri-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_3$ . [107°]. [1:2:2:3:4]. Formed by nitrating tri-bromo-toluene, [44°] (N. a. W.).

**Tri-bromo-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_3$  [1:3:2:1:6]. [215°]. Formed by nitrating tri-bromo-toluene [70°] (Wroblewsky, *A.* 168, 195).

**Tri-bromo-di-nitro-toluene**  $C_6H_2Me(NO_2)_2Br_3$  [1:2:2:3:4]. [217°–220°]. Formed by nitrating tri-bromo-toluene [44°] (Neville a. Winther, *B.* 13, 975).

**Tetra-bromo-nitro-toluene**  $C_6Me(NO_2)_2Br_4$  [1:4:2:3:5:6]. [213°] (N. a. W.); [227°] (S.). Formed by nitration of  $C_6H_4(CH_3)Br_4$  [117°] (Neville a. Winther, *C. J.* 37, 450). From (2, 4, 1)-bromo-nitro-toluene, bromine, and  $FeBr_3$  (Scheufelen, *A.* 231, 179).

**Tetra-bromo-nitro-toluene**  $C_6Me(NO_2)_2Br_4$  [1:2:3:4:5:6]. [212°]. From tetra-bromo-toluene, [111°].

**Tetra-bromo-nitro-toluene**  $C_6Me(NO_2)_2Br_4$  [1:5:2:3:4:6]. [216°]. By nitration of tetra-bromo-toluene, [108°].

**BROMO-NITRO-TOLUENE SULPHONIC ACIDS**  $C_6H_3MeBr(NO_2)SO_3H$ . The six following acids of this constitution have been described.

**I.** Formed by nitrating *o*-bromo-toluene sulphonic acid (Müller, *A.* 169, 42; Pagel, *A.* 176, 299). Deliquescent. —  $PbA'$ , 2aq. —  $NaA'$ , aq. —  $KA'$ . —  $BaA'$ , 2aq.

**II.** By the action of fuming  $HNO_3$  on (2, 1, 4)-bromo-toluene sulphonic acid or on (2, 1, 4)-*o*-toluidine sulphonic acid: in the latter case the resulting diazo-nitro-toluene sulphonic acid is boiled with  $HBrAq$  (Hayduck, *A.* 172, 319; 174, 347). Minute needles; may be reduced to (1, 3, 4)-*m*-toluidine sulphonic acid. —  $BaA'$ , 3aq. **Chloride**  $C_6H_2MeBr(NO_2)SO_2Cl$ . [220°].

**Amide**  $C_6H_2MeBr(NO_2)(SO_2NH_2)$ . Does not melt below 200°.

**III.** From *m*-bromo-toluenesulphonic acid and  $HNO_3$  (Wroblewsky, *A.* 168, 169). —  $CaA'$ , 4½aq. —  $BaA'$ , 3½aq. —  $PbA'$ , 3aq.

**IV.** Formed by nitrating (3, 1, 2 or 6)-*m*-bromo-toluene sulphonic acid (Weekwarth, *A.* 172, 200). —  $NaA'$ . —  $CaA'$ , 3aq. —  $BaA'$ , 3½aq.

**V.** Formed by nitrating (4, 1, 2)-*p*-bromo-toluene sulphonic acid (Hässelbarth, *A.* 169, 22). Deliquescent laminae. —  $AgA'$ . —  $BaA'$ , 2aq. —  $CaA'$ , 6aq. —  $PbA'$ , 3aq. —  $SrA'$ , 7aq.

VI. Formed by nitrating (4,1,3)-*p*-bromo-toluene sulphonic acid (H.). Deliquescent needles.— $\text{BaA}'_2$  aq.— $\text{PbA}'_2$  21 aq.— $\text{SrA}'_2$  5 aq.

**Di-bromo-nitro-toluene-di-sulphonic acid**  
 $\text{C}_6\text{H}_2\text{Br}_2(\text{NO}_2)\text{Me}.\text{SO}_3\text{H}$ . From *p*-bromo-toluene di-sulphonic acid and boiling fuming  $\text{HNO}_3$  (Kornatzki, *A.* 221, 197).— $\text{KA}'$  aq.— $\text{BaA}'_2$  3 aq.

**BROMO-NITRO-*m*-TOLUIC ACID**  $\text{C}_6\text{H}_4\text{BrNO}_2$ , i.e.  $\text{C}_6\text{H}_3\text{MeBr}(\text{NO}_2)(\text{CO}_2\text{H})$ . [176°]. From bromo-*m*-toluic acid and  $\text{HNO}_3$  (Fittig, *A.* 147, 84).— $\text{CaA}'_2$  3 aq.— $\text{BaA}'_2$  3 aq.

**Bromo-nitro-*p*-toluic acid**  
 $\text{C}_6\text{H}_4\text{MeBr}(\text{NO}_2)(\text{CO}_2\text{H})$  [4:2:3:1]. [200°]. S. 1 at 15°. Formed by boiling bromo-cymene (from thymol) with  $\text{HNO}_3$  (S.G. 1.3). Laminæ.— $\text{BaA}'_2$  4 aq (Filleti a. Crosa, *G.* 16, 297).

**Bromo-nitro-*p*-toluic acid**  
 $\text{C}_6\text{H}_4\text{MeBr}(\text{NO}_2)(\text{CO}_2\text{H})$  [4:3:2:1]. [170°-180°]. From bromo-*p*-toluic acid and fuming  $\text{HNO}_3$  (Landolph, *B.* 5, 269). Needles (from water).— $\text{BaA}'_2$  aq.

#### BROMO-NITRO-*o*-TOLUIDINE

$\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}$  [1:2:3:5]. [139°] (W.); [143°] (N. a. W.). Formed by nitrating bromo-acetyl-*o*-toluidine,  $\text{C}_6\text{H}_4\text{Me}(\text{NHAc})\text{Br}$  [1:2:5], and removing acetyl (Wroblewsky, *A.* 192, 206; Neville a. Winther, *C. J.* 37, 431). Gives, by nitrous gas and alcohol,  $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)\text{Br}$ , [81°] whence  $\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)\text{Br}$ , [35°].

#### Bromo-nitro-*o*-toluidine

$\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}$  [1:2:5:3]. [181° cor.]. By brominating  $\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)$  [1:2:3], [128°] (N. a. W.). Converted by nitrous gas and alcohol into  $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)\text{Br}$ , [81°] whence  $\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)\text{Br}$  [36°].

#### Bromo-nitro-*m*-toluidine

$\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}$  [1:3:6:5]. [88°]. Formed by nitrating bromo-acetyl-*m*-toluidine, and then removing acetyl by  $\text{H}_2\text{SO}_4$  (2 vols.) and water (1 vol.) (Neville a. Winther, *C. J.* 37, 630).

#### Bromo-nitro-*m*-toluidine

$\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}$  [1:3:2:6]. [183°]. Formed in small quantity in the preparation of its isomeride [181°].

#### Bromo-nitro-*p*-toluidine

$\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}$  [1:5:4:2]. [181°]. From the acetyl derivative by saponification.

**Acetyl derivative** [110°-121°]. Formed by nitration of bromo-acetyl-*m*-toluidine (Neville a. Winther, *C. J.* 37, 441).

#### Bromo-nitro-*p*-toluidine

$\text{C}_6\text{H}_3\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}$  [1:4:5:5]. [0.5-5°]. Got by saponifying its acetyl derivative. Orange needles. Converted by nitrous gas and alcohol into bromo-nitro-toluene [86°] (cf. Hand, *A.* 234, 157).

#### Acetyl derivative

[211°]. From bromo-acetyl-*p*-toluidine and  $\text{HNO}_3$ . Or from acetyl-*p*-toluidine by successive nitration and bromination (N. a. W.). White needles (from alcohol or dilute acetic acid) (Wroblewsky, *A.* 192, 202).

#### Di-bromo-nitro-*m*-toluidine

$\text{C}_6\text{H}_2\text{Me}(\text{NH}_2)(\text{NO}_2)\text{Br}_2$  [1:5:4:2:6]. [124°-130°]. From the acetyl derivative of bromo-nitro-*m*-toluidine [181°] by heating with  $\text{H}_2\text{SO}_4$  (2 vols.) and water (1 vol.) and subsequent treatment with bromine (Neville a. Winther, *C. J.* 37, 444).

**BROMO-NITRO-*m*-XYLENE**  $\text{C}_6\text{H}_3\text{Me}_2(\text{NO}_2)\text{Br}$ . [260°-265°]. From bromo-*m*-xylene and cold fuming  $\text{HNO}_3$ . Liquid (Fittig, *A.* 147, 81).

**Di-bromo-nitro-*o*-xylene**  $\text{C}_6\text{H}_2\text{Me}_2(\text{NO}_2)\text{Br}_2$  [1:2:8:4:5]. [141°]. Obtained by nitration of di-bromo-*o*-xylene  $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{Br}_2$  [1:2:4:5] with cold fuming  $\text{HNO}_3$ . Colourless needles (from alcohol) (Töhl, *B.* 18, 2561).

**Di-bromo-nitro-*m*-xylene**  $\text{C}_6\text{H}_2\text{Me}_2(\text{NO}_2)\text{Br}_2$ . [108°]. From di-bromo-*m*-xylene and  $\text{HNO}_3$ . Needles (F.).

**Di-bromo-nitro-*p*-xylene**  $\text{C}_6\text{H}_2\text{Me}_2(\text{NO}_2)\text{Br}_2$ . [112°]. From di-bromo-*p*-xylene and fuming  $\text{HNO}_3$  (F.). Needles.

**Di-bromo-di-nitro-*o*-xylene**  $\text{C}_6(\text{CH}_3)_4\text{Br}_2(\text{NO}_2)_2$  [1:2:1:5:3:6]. [c. 250°]. Small needles. Nearly insol. cold alcohol. Formed by nitration of di-bromo-*o*-xylene  $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{Br}_2$  [1:2:4:5] (Töhl, *B.* 18, 2561).

**BROMO-NITRO-XYLENE SULPHONIC ACID**  
 $\text{C}_6\text{H}_2\text{Me}_2\text{Br}(\text{NO}_2)(\text{SO}_3\text{H})$  [1:3:6:3:4]. From nitro-*m*-xylidine sulphonic acid by diazo-reaction (Sartig, *A.* 230, 341; *B.* 18, 2190). Rhombic plates, v. sol. water and alcohol.— $\text{BaA}'_2$  3 aq.— $\text{KA}'$  aq.

**BROMO-NONYLIC ACID** v. BROMO-ENNOIC ACID.

**DI-BROMO-OCTADECANE**  $\text{C}_{18}\text{H}_{36}\text{Br}_2$ . *Octadecylene bromide*. [24°]. Silvery plates. Sl. sol. alcohol. Formed by the addition of Br (1mol.) to octadecylene (Krafft, *B.* 17, 1373).

#### BROMO-OCTANE v. OCTYL BROMIDE

**Di-bromo-octane**  $\text{C}_{18}\text{H}_{36}\text{Br}_2$ . *Octylene bromide*. From Br and octylene derived from castor oil (Rubien, *A.* 112, 297) or that from paraffin (Thorpe a. Young, *Tr.* 21, 193). Non-volatile oil.

**Tetra-bromo-octane**  $\text{C}_8\text{H}_8\text{Br}_4$ . *Caprylidene tetra-bromide*. From bromo-octylene and Br. Oil.

**BROMO-OCTONENE**  $\text{C}_{18}\text{H}_{34}\text{Br}$ . [201°]. From  $\text{C}_{18}\text{H}_{34}\text{Br}$  (v. *supra*) and alcoholic KOH (R.).

**BROMO-OCTYL-BENZENE**  $\text{C}_{21}\text{H}_{42}(\text{C}_6\text{H}_5)\text{Br}$ . [285°-287°]. Formed by bromination of octylbenzene. Oil (Ahrens, *B.* 19, 2719).

**BROMO-OCTYLENE**  $\text{C}_{18}\text{H}_{34}\text{Br}$ . [185°]. From di-bromo-octane and alcoholic KOH (Rubien, *A.* 112, 297). With Br it gives an oily tri-bromodecane.

**Di-bromo-octylene**  $\text{C}_{18}\text{H}_{32}\text{Br}_2$ . S.G. 1.568. *Conylene bromide*. From conylene and Br (Wertheim, *A.* 123, 182).

#### BROMO-OCTYL-THIOPHENE

$\text{C}_8\text{SH}_2(\text{C}_6\text{H}_4)_2\text{Br}$ . [285°-290°]. Colourless oil solidifying to plates at 5°. V. sol. ether, insol. water. Formed by shakirg octyl-thiophene with bromine-water (Schweinitz, *B.* 19, 644).

**BROMO-OLEIC ACID**  $\text{C}_{18}\text{H}_{33}\text{BrO}_2$ . From di-bromo-stearic acid and alcoholic KOH (Overbeck, *A.* 140, 47).

**Di-bromo-oleic acid**  $\text{C}_{18}\text{H}_{32}\text{Br}_2\text{O}_2$ . From stearolic acid and Br (O.).

**BROMO-ORCIN**  $\text{C}_{12}\text{H}_9\text{Me}(\text{OH})\text{Br}$ . [155°]. From orcin and bromine-water (Lamparter, *A.* 134, 258). Crystals; m. sol. hot water, v. sol. alcohol and ether. Solutions are ppd. by lead subacetate.

#### Di-bromo-orcin

#### Methyl derivative

$\text{C}_9\text{H}(\text{CH}_3)(\text{OMe})(\text{OH})\text{Br}_2$ . [146°]. White needles. Prepared by bromination of the mono-methyl ether of orcin (Tiemann a. Streng, *B.* 14, 2002).

#### Di-methyl derivative

$\text{C}_9\text{H}(\text{CH}_3)_2(\text{OMe})_2\text{Br}_2$ . [160°]. Colourless plates. Sol. alcohol, ether, and benzene, insol. water and ligroin. Prepared by bromination of the di-methyl ether of orcin (*B.* 14, 2001).

**Tri-bromo-orein**  $C_6(OH)_3Br_3(OH)_2$ . [103<sup>3</sup>]. From orein and Br (Stenhouse, *Tr.* 1848, 87; Laurent a. Gerhardt, *A. Ch.* [3] 24, 317; Lamparter, *A.* 134, 257; Hesse, *A.* 117, 311; Stenhouse a. Groves, *A.* 203, 298). Is formed by heating penta-bromo-orein with formic acid. Needles; insol. water, sol. alcohol and ether.

**Diacetyl derivative** [143<sup>1</sup>]. White needles. Formed by the action of  $Ac_2O$  on penta-bromo-orein (Claassen, *B.* 11, 1440).

**Penta-bromo-orein**  $C_{12}H_3Br_5O_2$  i.e.  $C_6MeBr_2(OBr)_2$  [126<sup>2</sup>]. From orein and excess of bromine-water. Triclinic crystals (from  $CS_2$ ). At 160° it gives off  $Br_2$ , leaving  $C_{12}H_3Br_3O_2$  (Stenhouse, *A.* 163, 180; Liebermann a. Dittler, *A.* 169, 252).

**Bromo- $\beta$ -orein v. Bromo-betorein.**

**DI-BROMO-OXAL-ETHYLINE v. DI-BROMO-METHYL-ETHYL-GLYOXALINE.**

**BROMO-OXINDOLE v. OXINDOLE.**

**BROMO-OXY-ACRYLIC ACID.** *Phenyl derivative*  $C_6H_4BrO_2$  i.e.  $CHBrC(OPh).CO_2H$ . [138<sup>2</sup>]. From phenyl-oxy-rucobromic acid  $CHO.CBrC(OPh).CO_2H$  and KOH (Hill a. Stevens, *Am.* 6, 190). Needles (from water); v. e. sol. alcohol and ether.— $KAl^{+}$ .  $BaA^{+}$ . 5aq.— $CaA^{+}$ . 5aq.— $AgA^{+}$ .

**BROMO-OXY-AMIDO-BENZOIC ACID.** *Methyl derivative*  $C_6H_4BrNO_2$  i.e.  $C_6H_4Br(OMe)(NH_2)CO_2H$ . [185<sup>2</sup>]. *Bromo-amido-anisic acid*. From the corresponding nitro-acid. Needles, sl. sol. water.— $CaA^{+}$ . 5aq.— $BaA^{+}$ . 2aq.— $HA^{+}HCl$  [186<sup>2</sup>] (Balbiano, *G.* 14, 215).

**BROMO-DI-OXY-ANTHRAQUINONE**

$C_{12}H_2BrO_4$  i.e.  $C_{12}H_2(O_2(OH))_2Br_2$ . *Bromo-alizarin*. From alizarin (3 pts.) and Br (2 $\frac{1}{2}$  pts.) in  $CS_2$  at 190° (Perkin, *C. J.* 27, 401). Tubes of orange needles; may be sublimed. KOH aq. forms a blue solution, exhibiting the same absorption bands as alizarin.  $HNO_3$  forms phthalic acid. The same bromo-alizarin, or an isomeride, is formed by treating tri-bromo-anthraquinone with KOH. It melts at 280° (Diehl, *B.* 11, 190).

**Bromo-tri-oxy-anthraquinone**

$C_{12}H_2O_2(OH)_3Br$ . *Bromo-purpurin*. [276<sup>2</sup>]. From Br and purpurin, or its carboxylic acid, or by warming di-bromo-purpurin (v. *infra*) with conc.  $H_2SO_4$ . Red needles (Plath, *B.* 10, 615, 1619; Schunck a. Roemer, *B.* 10, 554).

(*B.* 1, 3, 2). **Di-bromo-oxy-anthraquinone**

$C_{12}H_2Br_2O_3$  i.e.  $C_{12}H_2(CO_2)_2C_6HBr_2(OH)$ . [208<sup>2</sup>]. Formed, together with di-bromo-phenol by heating tetra-bromo-phenol-phthalcin with excess of  $H_2SO_4$  at 150° (Bayer, *A.* 202, 136). Slender yellow needles; its alcoholic solution shows reddish fluorescence. Its solution in alkalis is reddish-brown. NaOH at 200° gives alizarin.

*Acetyl derivative*  $C_{12}H_2AcBr_2O_3$ . [190<sup>2</sup>].

**Di-bromo-di-oxy-anthraquinone**

$C_{12}H_2O_2(OH)_2Br_2$ . *Di-bromo-alizarin*. [170<sup>2</sup>]. Prepared by the action of Br in presence of I on alizarin. Small brownish-red needles. Combines with mordants (Diehl, *B.* 11, 190).

**Di-bromo-di-oxy-anthraquinone**

$C_{12}H_2O_2(OH)_2Br_2$ . *Di-bromo-purpuranthin*. [227°-230°] (P.); [231°] (S. a. R.). From purpuranthin and Br (Plath, *B.* 9, 1205). From munjistin and Br (Schunck a. Roemer, *C. J.* 33, 424). Orange needles (from HOAc). Warm conc.  $H_2SO_4$  forms bromo-purpurin.

**Salt.**— $(NH_4)_2A^{+}$ .

**Tri-bromo-tri-oxy-anthraquinone**

$C_{12}H_2O_2(OH)_3Br_3$ . *Tri-bromo-flavopurpurin*. [284<sup>2</sup>]. From flavopurpurin in HOAc and Br. Orange needles. Its alkaline solutions are orange (Schunck a. Roemer, *B.* 10, 1235).

**Tetra-bromo-di-oxy-anthraquinone**

$C_{12}H_2O_2(OH)_2Br_4$ . *Tetra-bromo-alizarin*. From alizarin and excess of iodine bromide at 180°. Does not combine with mordants (Diehl, *B.* 11, 191).

**BROMO-OXY-BENZOIC ACID**  $C_6H_4BrO_2$  i.e.  $C_6H_4Br(OH)CO_2H$  [3:2:1]. *Bromo-salicylic acid*. [181<sup>2</sup>] (L. a. G.); [220<sup>2</sup>] (H. a. E.). From the corresponding bromo-amido-benzoic acid by exchange of  $NH_2$  for OH (Hübner a. Fummeier, *Z.* 1871, 709) or from (3, 5, 2, 1)-bromo-amido-oxy-benzoic acid by eliminating  $NH_2$  (Tellmann a. Grothmann, *B.* 17, 2725). Needles, v. sl. sol. cold water, v. e. sol. alcohol.  $FeCl_3$  gives a violet colouration.— $CaA^{+}$ . 12aq.; v. sol. water.— $BaA^{+}$ . 3aq.; prisms.— $PbA^{+}$ . (H.).— $PbC_6H_4BrO_2$ .

**Bromo-o-oxy-benzoic acid**  $C_6H_4Br(OH)(CO_2H)$  [5:2:1]. [165<sup>2</sup>]. From salicylic acid and Br or  $PBr_3$  (Gerhardt, *A. Ch.* [3] 7, 217; Cahours, *A. Ch.* [3] 10, 341; 13, 99; Henry, *B.* 2, 275; H. a. E.). Also from the corresponding amido-bromo-benzoic acid (H. a. E.). Needles (from water).  $FeCl_3$  gives a violet colouration.  $BaA^{+}$ . 3aq.— $PbA^{+}$ .  $PbC_6H_4BrO_2$ .— $CuA^{+}$ .— $AgA^{+}$ .

*Methyl ether*  $MeA^{+}$ . [38<sup>2</sup>] (Henry); [61<sup>2</sup>] (Peratoner, *G.* 16, 405). [265<sup>2</sup>]. From methyl salicylate and Br or  $PBr_3$ . Trimetric prisms or needles. Coloured violet by  $FeCl_3$ .

*Methyl derivative*  $C_6H_4Br(OMe)CO_2H$ . [119<sup>2</sup>].— $BaA^{+}$ . 3aq.— $CaA^{+}$ . 4aq.  $AgA^{+}$  aq. *Methyl ether*  $C_6H_4Br(OMe)CO_2Me$ . [40<sup>2</sup>]. [295<sup>2</sup>] (P.).

*Ethyl derivative*  $C_6H_4Br(OEt)CO_2H$ . [130<sup>2</sup>].  $BaA^{+}$ . 4aq.— $CaA^{+}$ . 2aq. *Methyl ether*  $C_6H_4Br(OEt)CO_2Me$ . [49<sup>2</sup>]. [301<sup>2</sup>].

*Propyl derivative*  $C_6H_4Br(OPr)CO_2H$ . [62<sup>2</sup>]. *Methyl ether*  $C_6H_4Br(OPr)CO_2Me$ . [323<sup>2</sup>].

*Isopropyl derivative*  $C_6H_4Br(OPr)CO_2H$ . [101<sup>2</sup>]. *Methyl ether* (301<sup>2</sup>).

**Bromo-p-oxy-benzoic acid.** *Methyl derivative*  $C_6H_4Br(OMe)CO_2H$  [3:4:1]. *Bromo-anisic acid*. [214<sup>2</sup>]. [218<sup>2</sup> cor.].

**Formation.**—1. From anisic acid and Br (Laurent; Cahours, *A.* 56, 311; Salkowski, *B.* 7, 1013).—2. By oxidising the methyl ether of bromo-p-eg-soi (Schall a. Dralle, *B.* 17, 2531).

**Properties.** Needles; may be distilled or sublimed. Insol. water.

**Salts.**— $A^{+}A^{+}$ .— $BaA^{+}$ . 3aq.— $BaA^{+}$ . 4aq.— $CaA^{+}$ . 6aq.— $CuA^{+}$ . 2aq.— $NgA^{+}$ . 5aq.— $NaA^{+}$ . 2aq.— $PbA^{+}$ . 3aq.— $ZnA^{+}$ . 3aq.

*Ethyl ether*  $C_6H_4Br(OMe)(CO_2Et)$ . [74<sup>2</sup>] (Crespi, *G.* 11, 419).

*Amide*  $C_6H_4Br(OMe)(CO_2NH_2)$ . [186<sup>2</sup>]; insol. water.

**Bromo-p-oxy-benzoic acid.** *Methyl derivative*  $C_6H_4Br(OMe)CO_2H$ . [212<sup>2</sup>]. *Ethyl bromo-anisate* [74<sup>2</sup>] is converted into an isomeride [60<sup>2</sup>] by heating with NaOEt at 180° for 20 hours; on saponification it yields the acid which crystallises in needles, sl. sol. water. Potash fusion forms protocatechuic acid.  $HNO_3$  gives the methyl ether of (2,4,6,1)-bromo-di-nitro-phenol.

**Salt.**— $ZnA^{+}$ . 4aq (Balbiano, *G.* 11, 409).

**Ethyl ether EA'.** [60°] (*v. supra*). This acid is possibly identical with the preceding.

**Bromo-di-oxy-benzoic acid. Methyl derivative**  $C_6H_4Br(OH)(OMe)CO_2H$  [ $\alpha$ :4:3:1]. **Bromo-vanillic acid.** [193°]. From its acetyl derivative. Needles (containing aq). Acetyl derivative  $C_6H_4Br(OAc)(OMe)CO_2H$ . [167°]. From acetyl-vanillic acid and Br (Matsumoto, *B.* 11, 138).

**Di-methyl derivative**  $C_6H_4Br(OMe)_2CO_2H$  [ $\alpha$ :4:3:1]. **Bromo-veratric acid.** [181°]. From veratric acid and Br (M.).

**Methylene derivative**  $C_6H_4Br(OCH_2CO_2H)_2$  or  $C_6H_4(OCHBrCO_2H)_2$ . **Bromo-piperonylic acid.** [205°]. From bromo-piperonal and  $KMnO_4$  (Fittig u. Mielck, *A.* 172, 158).

**Bromo-di-oxy-benzoic acid**  $C_6H_4Br(OH)_2CO_2H$  [ $\alpha$ :1:3:5]. [253°]. From *s*-di-oxy-benzoic acid and bromine water (Barth u. Senhofer, *A.* 164, 115). Needles (containing aq). Potash-fusion forms gallic acid.  $Fe_2Cl_6$  gives a yellowish-brown colour.— $CaA'_2$  8aq.— $AgA'$ .

**Bromo-di-oxy-benzoic acid**  $C_6H_4Br(OH)_2CO_2H$  [ $\alpha$ :2:6:1]. [184°, anhydrous]. From *c*-di-oxy-benzoic acid in ether and Br (Zehenter, *M.* 2, 480). Prisms (containing aq).  $Fe_2Cl_6$  gives a violet colour to its aqueous solution.— $AgA'$  aq.  $BaA'_2$  7½aq.— $CaA'_2$  4½aq.— $PbA'_2$  3aq.— $KA'_2$  1½aq.

**Bromo-tri-oxy-benzoic acid**  $C_6H_3Br(OH)_3CO_2H$ . **Bromo-gallic acid.** [above 200°]. From gallic acid and Br (Hlasiwetz, *A.* 142, 250; Grimaux, *Z.* 1867, 431). Monoclinic; sl. sol. water.

**Di-bromo-o-oxy-benzoic acid**  $C_6H_2Br_2(OH)CO_2H$  [5:3:2:1]. **Di-bromo-salicylic acid.** [219°] (R.); [223°] (L. a. G.). From salicylic acid and Br or from (3,5,2,1)-bromo-amido-salicylic acid by the diazo-reaction (Cahours, *A. Ch.* [3] 10, 339; 13, 102; Rollwage, *B.* 10, 1707; Leilmann u. Grothmann, *B.* 17, 2727). Gives a violet colour with  $Fe_2Cl_6$ . Heated with dilute  $H_2SO_4$  it gives (3,5,2)-di-bromo-phenol [36°].— $BaA'_2$  4aq.

**Methyl ether**  $C_6H_2Br_2(OH)CO_2Me$ : [149°]; from methyl salicylate and Br (Peratoner, *G.* 16, 405). Long needles, sl. sol. alcohol.

**Methyl derivative**  $C_6H_2Br_2(OMe)CO_2H$ : [194°].—Salt  $BaA'_2$  2½aq. **Methyl ether**  $C_6H_2Br_2(OMe)CO_2Me$ : [53°]; needles.

**Ethyl derivative**  $C_6H_2Br_2(OEt)CO_2H$ : [156°]; white needles. **Methyl ether**  $C_6H_2Br_2(OEt)CO_2Me$ : [43°]; needles.

**Di-bromo-o-oxy-benzoic acid**  $C_6H_2Br_2(OH)CO_2H$  [5:3:2or6:1]. [218°]. From (4,3,1)-di-bromo-benzoic acid [229°] by nitration, reduction, and diazotisation (Smith, *B.* 10, 1706). Gives a violet colour with  $Fe_2Cl_6$ .

**Di-bromo-o-oxy-benzoic acid**  $C_6H_2Br_2(OH)CO_2H$ . [221°]. Formed as a by-product in converting (3,5,2,1)-bromo-nitro-benzoic acid [250°] into di-bromo-benzoic acid by the diazo-reaction (Hübner u. Jawric, *B.* 10, 1706).  $Fe_2Cl_6$  gives a violet colour.

**Di-bromo-p-oxy-benzoic acid**  $C_6H_2Br_2(OH)CO_2H$ . [268°]. From di-bromo-anisic acid and conc.  $HCl$  (Alceci, *G.* 15, 242). One of the products of the dry distillation of sodium di-bromo-anisate (Balbiano, *G.* 13, 69). Long needles, insol. water, sol. alcohol and ether.

$Fe_2Cl_6$  turns its solutions yellowish-red. Sodium-amalgam forms *p*-oxy-benzoic acid.— $CaA'_2$  3aq.

**Methyl derivative**  $C_6H_2Br_2(OMe)CO_2H$  [3:5:4:1]. **Di-bromo-anisic acid** [207°] (R.); [214°] (C.). From anisic acid, Br, and water at 120° (Reinecke, *Z.* 1866, 366; Crespi, *G.* 11, 425). Converted by prolonged action of Br and water into tri-bromo-anisol [87°].— $NaA'$  3aq.— $AgA'$ .— $BaA'_2$  4½aq. Ethyl ether  $C_6H_2Br_2(OMe)(CO_2Et)$ : [88°]; plates.

**Di-bromo-di-oxy-benzoic acid**  $C_6HBr_2(OH)_2CO_2H$ . [214°]. From (3, 2, 1)-di-oxy-benzoic acid and Br (Zehenter, *M.* 2, 475). Needles (containing aq); m. sol. hot water.  $Fe_2Cl_6$  turns its solution violet; conc.  $H_2SO_4$  gives a green colour. Heating with water forms di-bromo-resorcin.— $KA'_2$  3½aq.— $CaA'_2$  8½aq.— $PbC_6H_4Br_2O_4$ .— $CaA'_2$  aq.— $AgA'$ .

**Di-bromo-tri-oxy-benzoic acid**  $C_6Br_2(OH)_3CO_2H$ . **Di-bromo-gallic acid.** [140°] (G.); [150°] (E.). From gallic acid and Br (Grimaux, *Z.* 1867, 431; Fetti, *B.* 11, 1882).  $Fe_2Cl_6$  gives a blue-black colour in its aqueous solution.

**Tri-bromo-o-oxy-benzoic acid**  $C_6HBr_2(OH)CO_2H$ . **Tri-bromo-salicylic acid.** From Br and salicylic acid. Small prisms, insol. water (Cahours, *A. Ch.* [2] 13, 104).

**Tri-bromo-m-oxy-benzoic acid**  $C_6HBr_2(OH)CO_2H$ . [147°]. From *m*-oxy-benzoic acid (1 mol.) and Br (3 mols.) (Werner, *Bl.* [2] 46, 276).

**Tri-bromo-di-oxy-benzoic acid**  $C_6Br_2(OH)_2CO_2H$ . [183°]. From (5, 3, 1)-di-oxy-benzoic acid and Br (Barth u. Senhofer, *A.* 159, 225). Tables (from water). Potash-fusion reproduces *s*-di-oxy-benzoic acid.

**BROMO - o - OXY - BENZOIC ALDEHYDE**  $C_6H_3Br_2O_2$  i.e.  $C_6H_2Br_2(C=O)CHO$ . **Bromo-salicylic aldehyde.** [99°]. From salicylic aldehyde and Br or  $PBr_3$  (Löwig, *L.* 46, 57, 383; Piria, *A. Ch.* [2] 69, 281; Henry, *B.* 2, 275). Laminae; insol. water, sol. alcohol and ether. Combines with  $KHSO_5$ .

**Methyl derivative**  $C_6H_2Br_2(OMe)CHO$ . [114°]. From methyl-salicylic aldehyde and Br (Perkin, *A.* 145, 304). Flat prisms (from alcohol).

**Ethyl derivative**  $C_6H_2Br_2(OEt)CHO$ : [68°]; prisms.

**Bromo-p-oxy-benzoic aldehyde**  $C_6H_2Br_2(OH)CHO$ . [180°]. From *p*-oxy-benzoic aldehyde and Br. V. sol. alcohol and ether, v. sl. sol. water. Combines with  $KHSO_5$  (Heizfeld, *B.* 10, 2198).

**Di-bromo-o-oxy-benzoic aldehyde**  $C_6H_2Br_2(OH)CHO$ . **Di-bromo-salicylic-aldehyde.** Prisms. From salicylic aldehyde and Br (Heizfeld, *J. pr.* 32, 65).

**Phenyl-hydrazide**  $C_6H_2Br_2(OH)CH=N_2.NHPh$ : [148°]; v. sol. alcohol, benzene, ether, and  $CHCl_3$ , insol. water. The mono-acetyl-derivative  $C_6H_2Br_2(OAc)(CH=N_2.NHPh)$  forms fine needles [188°], nearly insoluble in ether. The di-acetyl derivative  $C_6H_2Br_2(OAc)_2CH=N_2.NHPh$  crystallises in white needles, [158°], easily soluble in ether; it is formed by brominating the di-acetyl derivative of the phenyl-hydrazide of salicylic aldehyde (Rossing, *B.* 17, 3008).

**Di-bromo-p-oxy-benzoic aldehyde**  $C_6H_2Br_2(OH)CHO$ . [181°]. From *p*-oxy-benzoic

aldehyde (1 mol.) and Br (2 mols.) (Werner, *Bl.* [2] 46, 277).

**BROMO-OXY-BUTYRIC ACID**  $C_4H_5BrO_3$ , [102°]. From di-bromo-butyric acid and baryta. Laminæ (Petrieff a. Eghis, *J. R.* 7, 179). —  $BaA''$ , —  $AgA'$ .

**Bromo-oxy-butyric acid**

$CH_3.CHBr.CH(OH).CO_2H$  or  $CH_3.CH(OH).CHBr.CO_2H$ . An uncrystallisable syrup obtained as a residue when  $\alpha\beta$ -di-bromo-butyric acid is distilled with water (C. Kolbe, *J. pr.* 133, 389; cf. Erlemeyer a. Müller, *B.* 15, 49).

**Bromo-oxy-butyric acid**

$CH_3.CHBr.CH(OH).CO_2H$  or  $CH_3.CH(OH).CHBr.CO_2H$ . [90°]. From  $\beta$ -methyl-glycidic acid  $O \begin{smallmatrix} CH_2CH_3 \\ \diagup \diagdown \\ CH_2CO_2H \end{smallmatrix}$  and  $HBr$  (Melikoff, *Bl.* [2] 43, 116). Prisms. Probably identical with the preceding.

**Bromo-oxy-iso-butyric acid**

$CH_3.Br.C(OH).Me.CO_2H$ . [101°]. Formed by boiling di-bromo-iso-butyric acid with water, and extracting with ether (K.). Also from  $HBr$  and  $\alpha$ -methyl-glycidic acid  $O \begin{smallmatrix} CH_2 \\ \diagup \diagdown \\ CH_2CO_2H \end{smallmatrix}$ . Needles; sol. hot benzene, insol.  $CHCl_3$  and  $CS_2$ . Not affected by boiling water. Reduced by the action of sodium amalgam on its aqueous solution, kept neutral by  $H_2SO_4$ , to oxy-iso-butyric acid, [79°].

**BROMO-OXY-CINNAMIC ACID** v. **BROMO-CUMARIC ACID**.

**BROMO (B. 4) OXY (Py. 4) ETHYL-QUINOLINE TETRA-HYDRIDE**  $C_{14}H_{15}Br(OH)EtN$ .

*Ethyl ether* [35°]; long monoclinic prisms,  $a:b:c = 0.7902:1.0:5828$ . Formed by bromination of ethyl-kairine (ethyl ether of oxy-ethyl-quinoline-tetra-hydride), or by ethylation of the ethyl-ether of bromo-oxy-quinoline-tetra-hydride. The picrate forms yellow needles [174°] (Fischer a. Renout, *B.* 17, 762).

**DI-BROMO-OXY-INDONAPHTHENE**

$C_{16}H_7Br_2O$  i.e.  $C_{16}H_7 \begin{smallmatrix} CO \\ \diagup \diagdown \\ CBr \end{smallmatrix} CBr$ . *Phenylene-di-bromo-acetylene ketone*. [123°]. Obtained by heating di-bromo-cinnamic acid  $C_6H_5.CBr.CO_2H$  with conc.  $H_2SO_4$ . Yellow needles.

*Oxim*  $C_6H_5.Br.(NOH)$ : [195°]; yellow needles.

*Anilide*: [170°]; red needles.

*Di-bromide*  $C_6H_5OBr_2$ : [124°]; prisms (Rosser, *B.* 20, 1273).

**BROMO-OXY-MALEIC ACID** *Phenyl derivative*  $CO_2H.CBr:C(OPh).CO_2H$ . [104°]. From the phenyl derivative of oxy-mucobromic acid and  $Ag_2O$  (Hill a. Stevens, *Am.* 6, 187). Needles. —  $AgA''$ .

**p-BROMO- $\omega$ -OXY-MESITYLENE**  $C_9H_7BrO$  i.e.  $C_6H_3(CH_3)_2.Br(CH_2OH)$  [5:3:4:1]. *p-Bromo-mesityl alcohol*. [66°]. Obtained from *p*- $\omega$ -di-bromo-mesitylene (*p*-mesityl bromide) by treatment with  $KOAc$  and saponification of the acetate. Pointed needles. V. e. sol. alcohol, ether, and benzene, sl. sol. cold petroleum-ether, insol. cold water. Decomposes on distillation with separation of  $H_2O$  and formation, amongst other products, of *p*-bromo-mesitylenic aldehyde  $C_6H_3(CH_3)_2.Br(CH=O)$ . By oxidising agents it is readily converted into *p*-bromo-mesitylenic acid [214°] (Schramm, *B.* 19, 213).

*iso-Bromo- $\omega$ , $\omega$ -di-oxy-mesitylene*

$C_9H_7Br(CH_2)(CH_2OH)$ . [121°]. S.  $3\frac{1}{2}$  at 100°. From the corresponding tri-bromo-mesitylene

(200°–215°) by boiling with water and  $PbCO_3$  (Colson, *A. Ch.* [6] 6, 98; *C. R.* 97, 177). Pearly scales; v. sl. sol. cold water, m. sol. alcohol. Boiling  $HClAq$  forms  $C_9H_7Br(CH_3)(CH_2Cl)$ , [75°].

**BROMO-OXY- $\beta$ -METHYL-CUMARILIC ACID**

$C_{11}H_9Br(OH) \begin{smallmatrix} (4) \\ \diagup \\ CMe \\ (2) \end{smallmatrix} \begin{smallmatrix} (1) \\ \diagdown \\ CO_2H \end{smallmatrix}$ . [221°]. Formed

by boiling bromo- $\beta$ -methyl-umbelliferon-di-

bromide  $C_6H_4.Br(OH) \begin{smallmatrix} CMe.Br.CHBr \\ | \\ O \end{smallmatrix} \begin{smallmatrix} CO \\ | \\ CO \end{smallmatrix}$  with alco-

holic  $KOH$ . Colourless needles. V. sol. alcohol and ether, sl. sol. benzene, insol. water. Cold  $H_2SO_4$  gives a colourless solution which becomes violet on heating.  $FeCl_3$  gives a yellow colouration with the alcoholic solution (Pechmann a. Cohen, *B.* 17, 2131).

**BROMO-OXY-METHYL-ETHYL-PYRIMIDINE**

**INE**  $C_7H_7C \begin{smallmatrix} N.C(OH) \\ \diagup \diagdown \\ N.C(CH_3) \end{smallmatrix} CBr$ . [195°]. Formed by bromination of oxy-methyl-ethyl-pyrimidine. Long colourless glistening needles. Sl. sol. water.  $C_6H_5N_2.Br(OH)aq$ : very soluble long white needles (Pinner, *B.* 20, 2362).

**BROMO-OXY-DI-METHYL-PYRIMIDINE**

$CH_3.C \begin{smallmatrix} N.C(OH) \\ \diagup \diagdown \\ N.C(CH_3) \end{smallmatrix} CBr$ . Formed by bromination of oxy-di-methyl-pyrimidine. The hydrobromide ( $BHBr$ ) forms colourless needles, m. sol. water, v. sol. alcohol (Pinner, *B.* 20, 2361).

(Py. 2,3,1)-**BROMO-OXY-METHYL-QUINOLINE**

**INE**  $C_{10}H_8NOBr$  i.e.  $C_9H_7 \begin{smallmatrix} CMe:CBr \\ \diagup \diagdown \\ N : C.OH \end{smallmatrix}$  ? *Bromo-*

*oxyquinoline*, or *bromo-quinoxyl*. [c. 258°]. Formed by the action of cold conc.  $H_2SO_4$  upon the anilide of bromo-aceto-acetic acid  $CH_3.C(OH):CBr.CONHPh$ . Also from (Py. 3, 1)-oxy-methyl-quinoline and bromine-water (Knorr, *B.* 17, 2875; *A.* 236, 91). Fine silky needles. Sl. sol. alcohol, ether, and chloroform. Dissolves in aqueous acids and alkalis.

**Tri-bromo-(Py.1)-oxy-(Py.3)-methyl-quinoline**  $C_9H_7MeBr_3(OH)N$ . [275°]. Formed by bromination of (Py. 1, 3)-oxy-methyl-quinoline. Insol. alcohol (Conrad a. Limpach, *B.* 20, 949).

**Bromo-(Py.3)-oxy-(Py.1,4)-di-methyl-quinoline**  $C_{11}H_{10}Br.NO$ . *Bromo-methyl-lepidone*. [172°]. From the corresponding oxy-dimethyl-quinoline and bromine-water (Knorr, *A.* 236, 110). Spherical aggregates of needles (from alcohol). Insol. water and  $NaOHaq$ , v. sol. dilute acids.

**BROMO-OXY-( $\alpha$ )-NAPHTHOIC ANHYDRIDE**

$C_{11}H_7BrO_2$  i.e.  $C_{10}H_7.Br \begin{smallmatrix} CO \\ \diagup \diagdown \\ O \end{smallmatrix}$  [192°]. Formed by

bromination of oxy-naphthoic anhydride

$C_{10}H_6 \begin{smallmatrix} CO \\ \diagup \diagdown \\ O \end{smallmatrix}$  dissolved in  $CS_2$ . Small white needles (Ekstrand, *B.* 19, 1139).

**Bromo-oxy-( $\alpha$ )-naphthoquinone**

$C_9H_5 \begin{smallmatrix} CO.C(OH) \\ \diagup \diagdown \\ CO.CBr \end{smallmatrix}$ . [197°].

*Formation*.—1. From di-bromo-( $\alpha$ )-naphthoquinone [151°] by boiling with aqueous  $NaOH$

or  $\text{Na}_2\text{CO}_3$ ; the yield being 60 p.c. of the theoretical (Diehl a. Merz, *B.* 11, 1064).—2. From oxy-(a)-naphthoquinone and Br.—3. Prepared by the action of alcoholic  $\text{H}_2\text{SO}_4$  on di-bromo-(a)-naphthoquinone-anilide, *p*-bromo-aniline being simultaneously produced (Baltzer, *B.* 14, 1901). 4. By the action of alkali upon bromo- $\beta$ -naphthoquinone (Zincke a. Gerland, *B.* 20, 1515).—5. By boiling bromo-amido-(a)-naphthoquinone  $\text{C}_6\text{H}_4\text{CO.C(NH}_2\text{).CBr}$  with dilute alkalis (Z.).—6. From bromo-oxy-(a)-naphthoquinone-imide  $\text{C}_6\text{H}_4\text{CO.C(NH).CBr}$  by boiling with conc. HCl or by treatment with alcoholic NaOH (Z.).

*Properties.*—Yellow needles; v. sl. sol. water, sl. sol. ether, v. sol. alcohol. Oxidation gives phthalic acid.

*Salts.*—KA' aq: red needles.—BA'  $\cdot$  S. 07 at 13°.—AgA'.

**Bromo-oxy-(a)-naphthoquinone.** [202°]. From the anilide [197°] of di-bromo-naphthoquinone [218°] by boiling with aqueous  $\text{Na}_2\text{CO}_3$  (Miller, *B.* [2] 43, 125). Oxidises to phthalic acid; it should therefore be identical with the preceding.

#### BROMO - OXY - (a) - NAPHTHOQUINONE

**IMIDE**  $\text{C}_6\text{H}_4\text{CO.C(NH).CBr}$  [c. 265°]. Formed by boiling bromo-amido-(a)-naphthoquinone-imide  $\text{C}_6\text{H}_4\text{CO.C(NH}_2\text{).CBr}$  with dilute NaOH.

Formed also by the action of  $\text{NH}_3$  upon bromo-( $\beta$ )-naphthoquinone. Brownish-red glistening needles. By boiling with conc. HCl or by treatment with alcoholic NaOH it is converted into bromo-oxy-(a)-naphthoquinone. The sodium-salt forms red needles; the salts of the heavy metals are sparingly soluble pps.

*Acetyl derivative:* [270°]; red hair-like needles (Zincke a. Gerland, *B.* 20, 1514).

#### BROMO-OXY-NAPHTHOQUINONE SUL-

**PHONIC ACID**  $\text{C}_6\text{H}_4\text{BrSO}_3\text{H}$  i.e.  $\text{C}_6\text{H}_4\text{O}_2\text{Br(OH)(SO}_3\text{H)}$ . From ( $\beta$ )-naphthosulphonic acid and Br, di-bromo-oxy-naphthoquinone being also formed in small quantity (Armstrong a. Graham, *C. J.* 39, 138; Armstrong a. Stretefeld, *C. J. Proc.* 1, 232).— $\text{BaC}_6\text{H}_4\text{BrSO}_3$ .

**BROMO-OXY-NICOTINIC ACID** v. Bromo-oxy-pyridine-carboxylic acid.

**BROMO-OXY-OCTOIC ACID**  $\text{C}_8\text{H}_7\text{BrO}_3$  i.e.  $\text{CH}_2\text{CHBr.CH}_2\text{CH(CO.H).CH}_2\text{CH(OH).CH}_3$ . *Bromo-oxy-di-propyl-acetic acid.*

S.G. 1.394. From di-allyl-acetic acid and HBr, the compound  $(\text{CH}_2\text{CHBr.CH}_2\text{CH}_2\text{CH}_2\text{CO.H})_2$  being probably first formed (Hjelt, *A.* 216, 73). Oil. Insol. cold water, v. sl. sol. warm water. Insol. cold NaOH. Boiled for a long time with water or aqueous  $\text{Na}_2\text{CO}_3$  it appears to form the

**OCTENOIC ACID.**

**Tri-bromo-oxy-octoic acid.** *Lactone*

di-allyl-acetic acid and bromine in chloroform (Hjelt, *A.* 216, 76). Oil. V. sol. ether. Insol. cold NaOH aq. Boiled with aqueous  $\text{Na}_2\text{CO}_3$  it forms  $(\text{CH}_2\text{CH(OH).CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{Na})_2$ .

**Tri-bromo-di-oxy-octoic acid.** *Lactone*  $\text{C}_8\text{H}_7\text{Br}_3\text{O}_3$  i.e.  $\text{CH}_2\text{Br.CHBr.CH}_2\text{CH(CO.H).CH}_2\text{CH(CH}_2\text{Br).O.CO}$ .

From so-called 'di-allyl-oxalic acid' and bromine (v. Oxy-octenoic acid) (Schatzky, *J. pr.* [2] 31, 485).

**Tetra-bromo-oxy-octoic acid**  $\text{C}_8\text{H}_4\text{Br}_4\text{O}_3$  i.e.  $(\text{CH}_2\text{Br.CHBr.CH}_2\text{CH(CO.H).CO}_2\text{H})_2$ . From so-called 'di-allyl-oxalic acid' and Br (Saytzeff, *A.* 183, 189). Oil: readily splits up into HBr and the preceding lactone.

*Ethyl ether* EAA'. Oil (Schatzky, *J. R.* 17, 73).

#### DI - BROMO - HEXA - OXY - DIPHENYL

*Methyl ether*  $\text{C}_{12}\text{H}_8\text{Br}_2(\text{OMe})_2$  [140°]. From the methyl ether of hexa-oxy-diphenyl and Br (Ewald, *B.* 11, 1623). Needles (from alcohol or HOAc); conc.  $\text{H}_2\text{SO}_4$  forms a blue solution.

**Tetra-bromo-di-oxy-diphenyl**  $\text{C}_{12}\text{H}_4\text{Br}_4\text{O}_2$  i.e.  $\text{C}_6\text{H}_4\text{Br(OH).C}_6\text{H}_4\text{Br}_3(\text{OH})$ . [264°]. From di-oxy-diphenyl and Br (Magatti, *B.* 11, 2267; 13, 225). Also by reduction of bromo-resoquinone (Bayer, *B.* 11, 1301). Fuming  $\text{HNO}_3$  forms brownish-red scales of  $(\text{C}_6\text{H}_4\text{Br}_2\text{O})_2$ . 'Tetra-bromo-diphenyl-quinone.'

*Acetyl derivative*  $\text{C}_{12}\text{H}_4\text{Ac}_2\text{Br}_4\text{O}_2$  [245°]; needles.

#### Tetra-bromo-tetra-oxy-diphenyl

$\text{C}_{12}\text{H}_4\text{Br}_4(\text{OH})_4$ , *Tetra-bromo-diresorein*. From tri-bromo-resoquinone  $\text{C}_6\text{H}_3\text{Br}_3\text{O}_2$  (?) and  $\text{H}_2\text{S}$  or Sn and HCl. Needles (from HOAc). Turns brown at 230° and decomposes at 280°. Insol. water, v. sol. alcohol and ether. Sodium-amalgam gives diresorein. Red-hot zinc-dust gives diphenyl.

*Acetyl derivative*  $\text{C}_{12}\text{H}_4\text{Br}_4(\text{OAc})_4$ . [195°]; needles (from alcohol) (Benedikt, *M.* 1, 352; *B.* 11, 2170).

**Deca-bromo-tetra-oxy-diphenyl**  $\text{C}_{12}\text{H}_4\text{Br}_{10}(\text{OBr})_4$ . Formed by adding Br and HCl to a solution of diresorein in aqueous potash (Benedikt a. Julius, *M.* 5, 179). Unstable crystals, gives off Br (2 mols.) at 185°.  $\text{SO}_2$  reduces it to  $\text{C}_6\text{H}_4\text{Br}_2(\text{OH})_4$ .

#### BROMO-p-OXY-PHENYL-ACETYLENE

*Methyl derivative*  $\text{C}_{10}\text{H}_7\text{Br(OMe).C}\equiv\text{CH}$ . [75°]. Formed by heating the methyl derivative of tri-bromo-*p*-oxy-phenyl-propionic acid  $\text{C}_6\text{H}_3\text{Br}_3(\text{OMe).CHBr.CHBr.CO}_2\text{H}$  with aqueous KOH (30 p.c.). Plates. Gives an unstable greenish-yellow compound with ammoniacal  $\text{CuCl}_2$  (Fiegel, *B.* 20, 2538).

#### DI-BROMO-DI-OXY-DI-PHENYL-AMINE

$\text{C}_{12}\text{H}_8(\text{OH).N.H.C}_6\text{H}_4\text{Br}_2\text{OH}$  [4:6:2:1]. *Leuco-di-bromo-quinone-phenol-imide*. [170°]. Colourless prisms. V. sol. all ordinary solvents, except water. Formed by reduction of di-bromo-quinone-phenol-imide (Möhlau, *B.* 16, 2848).

*a* - *β* - *eso* - *eso* - **TETRA - BROMO - o - OXY - β - PHENYL-BUTYRIC ACID.** *Methyl derivative*  $\text{C}_6\text{H}_4\text{Br}_2(\text{OMe).CHBr.CMeBr.CO}_2\text{H}$ . [c. 200°]. From ( $\alpha$ ) or ( $\beta$ ) methoxy-phenyl-crotonic acid and bromine vapour (Perkin, *C. J.* 39, 434). Crystalline powder (from chloroform).

**Tetra-bromo-di-oxy-di-phenyl-methane**  $\text{C}_{12}\text{H}_4\text{Br}_4\text{O}_2$  i.e.  $\text{CH}_2(\text{C}_6\text{H}_4\text{Br}_2\text{OH})_2$  [225°]. From di-oxy-di-phenyl-methane and bromine-water

In ethereal solution it forms an unstable crystalline compound with hydric bromide  $C_{10}H_7Br_2O_2$  (Beck, B. 10, 1837).

**BROMO-OXY-PHENYL-METHYL-PYRAZOLE**  
 $C_6H_5N \begin{smallmatrix} \diagup CO \\ \diagdown N=CHBr \end{smallmatrix} \diagdown$ . *Bromo-phenyl-methyl-pyrazolone*. [c. 130°]. From oxy-phenyl-methyl-pyrazole and Br in glacial acetic acid (Knorr, A. 238, 176). Sol. alkalis, and dilute acids; insol. water. Sl. sol. ether, v. sol. glacial HOAc and chloroform. In alcoholic solution it slowly forms pyrazole-blue.  $FeCl_3$  forms pyrazole-blue.

**Di-bromo-oxy-phenyl-methyl-pyrazole**  
 $C_{10}H_6N_2OBr_2$  i.e.  $PhN \begin{smallmatrix} \diagup CO \\ \diagdown N=CHBr \end{smallmatrix} \diagdown$ . *Di-bromo-phenyl-methyl-pyrazolone*. [80°]. From oxy-phenyl-methyl-pyrazole (1 pt.) and Br (2 pts.) in acetic acid solution (Knorr, A. 238, 177). Sol. alcohol, HOAc, ether, and  $CHCl_3$ ; insol. water, alkalis, and acids. Not attacked by  $FeCl_3$ . Reduced by Sn and HCl or fuming HI to oxy-phenyl-methyl-pyrazole.

**BROMO-OXY-PHENYL-METHYL-PYRIMIDINE**  
 $C_{11}H_8N_2BrO$  i.e.  $C_6H_5 \begin{smallmatrix} \diagup N:C(OH) \\ \diagdown N:C(CH_2Br) \end{smallmatrix} \diagdown$ . [260°]. Formed by bromination of oxy-phenyl-methyl-pyrimidine. Glistening needles (Pinner, B. 20, 2361).

**BROMO-o-OXY-PHENYL-PROPIOLIC ACID.**  
*Methyl derivative*  
 $C_6H_5(OMe)Br.C_6H_4.CO_2H$ . [168°] (with decomposition). From the methyl derivative of tri-bromo-oxy-phenyl-propionic acid (q.v.). Short white needles (from benzene).

**BROMO-o-OXY-β-PHENYL-PROPIONIC ACID**  $C_6H_5BrO_2$  i.e.  $C_6H_5Br(OH).CH_2CH_2.CO_2H$ . *Bromo-melilotic acid*. [142°]. From its anhydride by boiling with water. Rectangular tables (from chloroform). Sol. alcohol, sl. sol. water. Changes on melting into its anhydride.

*Anhydride*  $C_6H_4Br \begin{smallmatrix} O \\ \diagup CH_2CH_2 \end{smallmatrix} \diagdown CO$ . [106°].

From melilotic anhydride and Br in  $CS_2$  in the cold (Fittig u. Hochstetter, A. 226, 361). Thick prisms (from chloroform). Bromine is not taken out by boiling alkalis. Sol. alcohol and chloroform, sl. sol.  $CS_2$ . Slowly converted by boiling water into bromo-melilotic acid.

**α-Bromo-β-oxy-β-phenyl-propionic acid**  
 $C_6H_5CH(OH).CHBr.CO_2H$ . [122°]; [125°, anhydrous]. From αβ-di-bromo-β-phenyl-propionic acid by boiling with water (Glaser, A. 147, 814). Thin laminae (containing aq.). Boiled with very dilute  $Na_2CO_3$  it gives phenyl-acetic aldehyde:

The yield is 75 p.c. of the theoretical, but some phenyl-glyceric acid is also formed:

### ββ-Bromo-α-oxy-α-phenyl-propionic acid

$CHBr_2.CPh(OH).CO_2H$ . *Di-bromo-atrolactic acid*. [167°]. Prepared by dissolving di-bromopyruvic acid and benzene in cold  $H_2SO_4$ . Long needles or four-sided tables. Sol. benzene and  $CS_2$ , sl. sol. cold water. By boiling with water it decomposes into  $CO_2$ , HBr, and α-bromoacetophenone ( $C_6H_5.CO.CH_2Br$ ). On reduction it gives atrolactic acid (Böttger, B. 11, 1265).

• **Bromo-di-oxy-phenyl-propionic acid**

*Methylene ether*  $C_{10}H_7BrO_2$  or

*pipero-propionic acid*. [140°]. From sodium bromo-(β)-hydro-piperate and  $KMnO_4$  (Weinstein, A. 227, 41). Monoclinic crystals (from ether) sol. alcohol, sl. sol. water.— $CaA'$ .

**Di-bromo-o-oxy-phenyl-propionic acid**

$C_6H_4Br_2O_2$ . *Di-bromo-melilotic acid*. [115°]. From melilotic acid and Br (Zwenger, A. Suppl. 5, 116). Needles; may be distilled.— $BaA'$ . 5aq

• **α-β-Di-bromo-o-oxy-phenyl-propionic acid.**

*Di-bromide of coumaric acid.*

*Methyl derivative*

$C_6H_4(OMe).CHBr.CHBr.CO_2H$ . [162°]. S. ( $CHCl_3$ ) 2-7 at 17°. From the methyl derivative of coumaric acid  $C_6H_4(OMe).CH.CH.CO_2H$  and Br. V. sol. ether. Decomposed by aqueous alkalis. With bromine vapour it gives rise to  $C_6H_4Br_2(OMe).CHBr.CHBr.CO_2H$  [c. 202°]. Crystals (from benzene) (Perkin, C. J. 39, 420; Fittig u. Ebert, A. 216, 157). Strong potash (1:1) forms  $C_6H_4(OMe)C_2HBr.CO_2H$  [171°].

*Di-methyl ether*

$C_6H_4(OMe).CHBr.CHBr.CO_2Me$ .

(a)-compound [125°]. S. ( $CS_2$ ) 3-4.

(β)-compound [68°]. S. ( $CS_2$ ) 4.

These two compounds are formed together by acting on the isomeric methoxy-phenyl-acrylates of methyl with bromine in  $CS_2$ . But the (α)-isomeride gives chiefly that melting at 125° while the (β)-isomeride forms chiefly the other (Perkin C. J. 39, 424). Alcoholic potash converts both into methoxy-phenyl-bromo-acrylic acid.

*Ethyl derivative*

$C_6H_4(OEt).CHBr.CHBr.CO_2H$ . [155°]. S. ( $CS_2$ ) 1-03 at 18°. From the ethyl derivatives of coumaric and of coumaric acids by Br (F. A. E.). Small crystals (from  $CS_2$ ).

*Di-ethyl ether*

$C_6H_4(OEt).CHBr.CHBr.CO_2Et$ . [78°]. From  $C_6H_4(OEt).CH : CH.CO_2Et$  and Br in  $CS_2$  (P.).

**eso-Di-bromo-p-oxy-β-phenyl-propionic acid**  
 $HO.C_6H_4Br_2.CH_2.CO_2H$ . *Di-bromo-hydro-p-coumaric acid*. [108°]. From aqueous hydro-p-coumaric acid and cold bromine-water (Stöhr, A. 225, 64). Needles (from acetic acid).

Salts.— $(NH_4)_2C_6H_4Br_2O_2$ — $AgC_6H_4BrO_2$ .

• **αβ-Di-bromo-p-oxy-phenyl-propionic acid**  
 $C_6H_4(OH).CHBr.CHBr.CO_2H$ . *p-Coumaric-acid-di-bromide*.

*Methyl derivative*

$C_6H_4(OMe).CHBr.CHBr.CO_2H$  : [149°]; colourless crystals. Formed by combination of the methyl derivative of p-coumaric acid with Br.

*Di-methyl ether*

$C_6H_4(OMe).CHBr.CHBr.CO_2Me$  : [118°]; m. sol. ether and chloroform. Formed by combination of the di-methyl ether of p-coumaric acid with bromine. When boiled with aqueous

potash solution (80 p.p.) it is converted into the methyl derivative of  $\alpha$ -bromo-*p*-vinyl-pheno  $C_6H_4(OMe).CH:CHBr$  (Valentini, *G.* 10, 424 Eigel, *B.* 20, 2536).

**Di-bromo-di-*iso*-oxy- $\alpha$ -di-phenyl-propionic acid**  $C_{12}H_{12}Br_2O_4$ . **Di-bromo-di-phenopropionic acid.** Formed by bromination of di-pheno-propionic acid  $CH_3.C(C_6H_5(OH))_2.CO_2H$ . Amorphous powder. Sol. alcohol, insol. water.

**Di-acetyl derivative**  $C_{12}H_{10}Br_2(OAc)_2$ ; insoluble light yellow powder (Böttger, *B.* 16, 2073).

**Tri-bromo-*p*-oxy-phenyl-propionic acid**  $C_6H_3Br(OH).CHBr.CHBr.CO_2H$ . **Bromo-*p*-coumaric-acid- $\alpha$ -bromide.** [188°]. Obtained by the action of bromine upon *p*-coumaric acid. Needles. By alcoholic KOH it is converted into tri-bromo-oxy-ethyl-benzene  $C_6H_3Br(OH).CHBr.CH_2Br$ .

**Methyl derivative**  $C_6H_3Br(OMe).CHBr.CHBr.CO_2H$ : [162°]; needles. Formed by the action of bromine upon the methyl derivative of *p*-coumaric acid  $C_6H_4(OMe).CH:CH.CO_2H$ . By heating with aqueous KOH (30 p.c.) it is converted into bromomethoxy-phenyl-acetylene  $C_6H_3Br(OMe).C\equiv CH$  (Eigel, *B.* 20, 2534).

**$\alpha$ - $\beta$ -tri-bromo-*o*-oxy-phenyl-propionic acid** **Methyl derivative**  $C_6H_3Br(OMe).CHBr.CHBr.CO_2H$ . [185°-188°]. S. (chloroform) 42. From methyl-*o*-coumaric acid and bromine vapour (Perkin, *C. J.* 39, 417). White nodules (from benzene).

Boiled with sodium acetate it gives off  $CO_2$  forming the methyl derivative of *o*-*exo*-dibromo-*o*-vinyl-phenol,  $C_6H_3Br(OMe).C_2H_2Br$ , a viscid oil. Strong KOH (1:1) gives the methyl derivative of bromo-oxy-phenyl-propionic acid (*q. v.*).

**Tetra-bromo-*o*-oxy-phenyl-propionic acid** **Methyl derivative**  $C_6H_2Br_2(OMe).CHBr.CHBr.CO_2H$ . [202°]. From the preceding and Br (P.).

**DI-BROMO-DI-OXY-DI-PHENYL SULPHIDE.**  $S(C_6H_4Br.OH)_2$ . [173°]. From *p*-bromo-phenol and  $SCl_2$  in  $CS_2$  (Tassinari, *G.* 17, 91). Amorphous, reduced by zinc-dust to  $S(C_6H_5OH)_2$ . [128°].

**DI-BROMO-DI-OXY-DI-PHENYL SULPHONE.** **Di-methyl derivative**  $SO_2(C_6H_3(OMe)Br)_2$ . [166°]. From  $SO_2(C_6H_4OMe)_2$  and Br. Small plates, v. sol. boiling alcohol (Annheim, *A.* 172, 48).

**Di-ethyl derivative**  $SO_2(C_6H_3(OEt)Br)_2$ . [183°].

**Di-isoamyl derivative**

$SO_2(C_6H_3(OC_2H_5)_2Br)_2$ . [100°].

**Tetra-bromo-di-oxy-di-phenyl sulphone**  $SO_2(C_6H_3Br_2OH)_2$ . [279°]. From di-oxy-di-phenyl-sulphone and Br. Thick monoclinic prisms (from alcohol).

**TETRA-BROMO-OXY-PHENYL-VALERIC ACID.** **Methyl derivative**

$C_6H_2Br_2(OMe).CHBr.CEtBr.CO_2H$ . [159°]. From (a) and (B) methoxy-phenyl-angelic acids and bromine vapour. Crystallised from light petroleum (Perkin, *C. J.* 39, 437).

**Di-bromo-di-oxy-phenyl-valeric acid** **Methylene derivative**  $C_{12}H_{12}Br_2O_4$ , i.e.

$CH_2<\overset{O}{\underset{O}{C}}>C_6H_3C_6H_4Br_2.CO_2H$ . **Di-bromo-piper-hydronic acid.** [136°-140°]. From (a)-hydro-

piperic acid and Br (Fittig a. Mielck, *A.* 172, 159; Weinstein, *A.* 227, 83). Warm NaOHAq gives piperic acid. Sodium-amalgam gives hydro-piperic acid.

**Tetra-bromo-di-oxy-phenyl-valeric acid** **Methylene derivative**

$CH_2<\overset{O}{\underset{O}{C}}>C_6H_3CHBr.CHBr.CHBr.CHBr.CO_2H$ .

**Tetra-bromo-piperhydronic acid.** [160°-165°]. From piperic acid and Br (F. a. M.). Alkalies give HBr and piperonal  $CH_3O_2C_6H_3CHO$ . Boiling water produces HBr and 'di-bromo-piperinide'  $C_{12}H_{12}Br_2O_4$  [136°]; this body crystallises from alcohol in prisms, insol. water and alkalies, converted into piperonal by boiling aqueous  $Na_2CO_3$ . Further treatment with water converts di-bromo-piperinide into bromo-oxy-piperinide  $C_{12}H_{12}BrO_4$  [132°], which separates from alcohol in monoclinic crystals, insol. aqueous  $Na_2CO_3$ .

**BROMO-DI-OXY-PHTHALIDE.** **Di-methyl derivative**  $C_{10}H_8BrO_3$ , i.e.

$C_6H_3Br(OMe)_2<\overset{CO}{\underset{CH_2}{C}}>O$  [ $\alpha$ :6:5:2].

**Bromo-pseudo-mecconine.** [142°]. White flocculent solid (Salomon, *B.* 20, 887).

**BROMO-OXY-PIPERINIDE v. TETRA-BROMO-DI-OXY-PHENYL-VALERIC ACID.**

**$\alpha$ -BROMO- $\beta$ -OXY-PROPIONIC ACID**

$C_6H_3BrO_3$ , i.e.  $CH_2(OH).CHBr.CO_2H$ . **Bromo-hydracrylic acid.** Formed by warming silver  $\alpha\beta$ -di-bromo-propionate with water (Beckurts a. Otto, *B.* 18, 236). Syrup; converted by moist  $Ag_2O$  into glyceric acid. Salt.— $ZnA_2$ .

**$\beta$ -Bromo- $\alpha$ -oxy-propionic acid**  $CH_2Br.CH(OH).CO_2H$ .  **$\beta$ -Bromo-lactic acid.** [90°]. From  $\alpha\gamma$ -acrylic acid and HBr (Melikoff, *B.* 13, 958). Prisms (from ether); miscible with water.

**Di-ethyl ether**  $CH_2Br.CH(OEt).CO_2Et$ . From  $CH_2Br.CHBr.CO_2Et$  and  $NaOEt$  (Michael, *J. p.* [2] 35, 136).

**$\alpha\beta$ -Di-bromo- $\alpha$ -oxy-propionic acid**  $CH_2Br.CHBr(OH).CO_2H$ . **Di-bromo-lactic acid.** [98°]. From acrolein dibromide and cold dilute  $HNO_3$  (Linnemann a. Peni, *B.* 8, 1101).

**$\beta\beta$ -Di-bromo- $\alpha$ -oxy-propionic acid**  $CHBr_2.CH(OH).CO_2H$ . **Di-bromo-lactic acid.** From the nitrile and  $HClAq$ . Syrup.

**Nitrile**  $CHBr_2.CH(OH).CN$ . From di-bromo-aldehyde and  $HCN$ . Oil (Pinner, *A.* 179, 71; *B.* 7, 1501).

**$\beta\beta\beta$ -Tri-bromo-oxy-propionic acid**  $CBBr_2.CH(OH).CO_2H$ . **Tri-bromo-lactic acid.** [143°]. From bromal,  $HCN$ , and  $HCl$  (Pinner, *B.* 7, 1501; Wallach, *A.* 193, 50).

**Ethyl ether**  $EtA$  [46°]; prisms.

**Nitrile**  $CBBr_2.CH(OH).CN$ . From bromal hydrate and conc.  $HClAq$ . Prisms, v. sol. water.

**Tri-bromo-ethylidene ether v. Bromalide.**

**Tri-chloro-ethylidene ether**  $CCl_3.CH(C_2H_4BrO_3)_2$ . [134°]. Formed by heating the acid with chloral.

**DI-BROMO-DI-OXY-PROPYL-BENZENE v. Bromo-eugenol.**

**Di-bromo-tri-oxy-propyl-benzene.** **Di-bromo-propyl-pyrogallol.**

**Di-methyl derivative**  $C_{11}H_{14}Br_2O_4$ , i.e.  $C_6(C_2H_4Br_2(OH)(OMe))_2$ . [109°]. **Acetyl derivative**  $C_6(C_2H_4Br_2(OAc)(OMe))_2$ . [102°].

**Methyl di-acetyl derivative**  
 $C_6(C_2H_5)_2Br_2(OAc)_2(OMe)$ . [79°]. These compounds are formed by brominating the corresponding derivatives of tri-oxy-propyl-benzene (Hofmann, B. 11, 331; Brezina, M. 4, 492; Pastrovich, M. 4, 185).

**DI-BROMO-DI-OXY-DI-PROPYL-MALONIC ACID**  $(CH_2Br.CH(OH).CH_2)_2C(CO_2H)_2$ .

From di-allyl-malonic acid in glacial HOAc by Br (Hjelt, B. 15, 625; A. 216, 61). The tetrabromide  $(CH_2Br.CHBr.CH_2)_2C(CO_2H)_2$  is first formed, but splits off 2HBr. Small plates (from alcohol). Insol. cold water, sl. sol. boiling water, v. sol. warm alcohol, sl. sol. ether. When boiled with baryta it ought to form  $Ba(CO_2)_2C(CH_2.CH(OH).CH_2OH)_2$  but this splits off BaCO<sub>3</sub>, forming the lactonic acid:

**DI-BROMO-OXY-PYRIDINE**  $C_5H_4Br_2NO$  i.e.  $C_5H_4Br_2(OH)N$ . Prepared by heating piperidine with Br and water to 200° (Hofmann, B. 12, 984). Glistening scales. Sl. sol. water, ether, and alcohol. Sol. aqueous acids and alkalis.—(BHCl).PtCl<sub>4</sub>: long needles.— $C_5H_4AgBr_2ON$ : white pp.

*Methyl derivative*: [193°]; long needles.

**Di-bromo-oxy-pyridine**  $C_5H_4Br_2(OH)N$ . [207°]. Long white needles. Formed by adding bromine-water to a solution of oxy-pyridine [107°] (Königs a. Geigy, B. 17, 591).

**Di-bromo-oxy-pyridine**  $C_5H_4Br_2(OH)N$ . [c. 200°]. Formed by the action of bromine-water upon (β)-oxy-pyridine [125°]. Colourless needles. V. sol. water and alcohol, nearly insol. benzene. FeCl<sub>3</sub> gives a violet colouration.

*Salts*.—17HBr: small white silky needles. B'H<sub>2</sub>SO<sub>4</sub>\*: easily soluble plates. —B'H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>\*: needles sl. sol. alcohol. The picate forms yellow needles (Fischer a. Renout, B. 17, 1898).

**BROMO-OXY-PYRIDINE-CARBOXYLIC ACID**  $C_5H_4N(Br)(OH)CO_2H$  [1:2:2:5]. *Bromo-oxy-nicotinic acid*. [296°]. Obtained by saponification of the methyl-ether, which is formed by the action of aqueous NH<sub>3</sub> upon the methyl-ether of bromo-cumalic acid. Sl. sol. hot water, nearly insol. ether, alcohol, and acetic acid.

*Methyl ether*  $C_5H_4N(Br)(OH)CO_2Me$ . [222°]. Slender glistening needles. Sol. hot water and hot alcohol.

*Phenyl derivative of the methyl-ether*  $C_5H_4N(Br)(OPh)CO_2Me$ . [183°]. Formed by the action of aniline on the methyl-ether of cumalic acid in alcoholic solution. Distils without decomposition; white glistening needles, sol. alcohol and ether, insol. water (Pechmann a. Welsh, B. 17, 2398).

**DI-BROMO-OXY-QUINOLINE**

$C_8H_6Br_2(OH)N$ . [195°]. Prepared by the action of bromine-water on a solution of oxy-quinoline (Bedall a. Fischer, B. 14, 1367). White silky needles. Sol. alcohol, ether, benzene, CS<sub>2</sub>, nsol. water, ligroin, and dilute acids.

V. also BROMO-CARBOSTYRIL.

**BROMO-(B.4)-OXY-QUINOLINE TETRAHYDRIDE**. *Ethyl ether*  $C_8H_6Br_2(OEt)N$ .

[45°]. Obtained by adding bromine to a cooled chloroform solution of (B.4)-ethoxy-tetra-hydro-quinoline. Long triclinic crystals. The hydrochloride crystallises in felted needles, the sulphate in colourless plates, and the oxalate in prisms. The picate forms sparingly soluble yellow needles [108°]. The nitrosamine forms glistening plates [86°] (Fischer a. Renout, B. 17, 760).

**DI-*p*-BROMO-DI-OXY-QUINONE**

$C_6Br_2(OH)_2O_2$  [1:4:2:5:3:6]. *Bromanilic acid*.

*Formation*.—1. By dissolving di-, tri-, or tetra-bromo-quinone in potash (Stenhouse, A. 91, 311; Sarauw, A. 209, 115).—2. By heating the sodium salt of di-oxy-quinone-di-*p*-carboxylic acid with conc. HBr.—3. Together with tetra-bromo-quinone by heating (1,3,5,2)-tribromo-phenol with pyrosulphuric acid at 115°; the reaction is anomalous as the two Br should remain *m* to one another (Salzmänn, B. 20, 1997), v. also DI-CHLORO-DI-OXY-QUINONE.

*Properties*.—Monosymmetrical dark-red needles or bronzy plates. Converted by Br into hexa-bromo-acetone. A neutral solution of the Na salt gives the following reactions:—CaCl<sub>2</sub>: brown pp.—BaCl<sub>2</sub>: yellowish-brown pp.—FeSO<sub>4</sub> and NiSO<sub>4</sub>: greenish-grey pp.—FeCl<sub>3</sub>: brownish-black.—Co(NO<sub>3</sub>)<sub>2</sub>: brown.—Pb(OAc)<sub>2</sub>: reddish-brown.—CuSO<sub>4</sub>: greenish-brown.—AgNO<sub>3</sub> and Hg<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>: red. HgCl<sub>2</sub>: no pp.

*Salts*.—Na<sub>2</sub>A\* 4aq: asymmetric crystals.—K.A\* 2aq: asymmetric crystals.—K.A\* aq (Hantzsch, B. 20, 1303; Hantzsch a. Schnitzer, B. 20, 2040, 2279).

**Di-bromo-di-oxy-quinone**. *Di-methyl derivative*  $C_6Br_2(OMe)_2O_2$ . [175°] (Hofmann, B. 11, 332).

**Tri-bromo-oxy-quinone**  $C_6(OH)Br_3O_2$ . [207°]. From oxy-hydroquinone and Br (B. th. a. Schreder, M. 5, 593). Orange grains; sol. alcohol and CHCl<sub>3</sub>.

**DI-BROMO-OXY-TOLUIC ACID**. *Methyl ether*  $C_8H_6Br_2Me(OMe).CO_2H$  [2:4:2:1]. [194°]. From the methyl derivative of di-bromo-thymol by oxidation (Paternò a. Canzoneri, G. 10, 233).

**DI-BROMO-OXY-TOLUQUINONE**

$C_8MeBr_2(OH)O_2$ . [197°]. Formed in small quantity by the action of dilute KOH on tri-bromo-toluquinone (Spica a. Magnanini, G. 13, 312).

**BROMO-OXY-TOLYL-PHENYL-KETONE-CARBOXYLIC ACID**

$C_8H_4(CO_2H).CO.C_6H_4(CH_3)(Br)OH$ . [228°]. Prepared by the action of Br and acetic acid on an alcoholic solution of *o*-cresol-phthalate. Small prisms. By heating with H<sub>2</sub>SO<sub>4</sub> to 130° it is readily converted into bromo-oxy-methyl-anthraquinone. *Chloride* [208°] (Fraude, B. 12, 239).

**DI-*β*-BROMO-*α*-OXY-*α*-TOLYL-PROPIONIC ACID**  $C_{10}H_{10}Br_2C_3$  i.e.  $CHBr_2.C(C_2H_5)(OH).CO_2H$ .

*Di-bromo-*eso*-methyl-atrolactic acid*. [163°]. Prisms or needles. Prepared by dissolving di-bromo-pyruvic acid and toluene in H<sub>2</sub>SO<sub>4</sub> at 0°. By hot water it is decomposed into CO<sub>2</sub> and tolyl bromo-methyl ketone  $C_8H_7.CO.CH_2Br$ . On reduction it gives *eso*-methyl-atrolactic acid (Böttger, B. 14, 1597).

**BROMO-OXY-VALERIC ACID**. *Lactone*.  $CH_2.CH.CHBr.CH_2.CO.O$ . From *β*-di-bromo-

valeric acid by boiling with water (Messer.

schmidt, A. 208, 102). Non-volatile oil; converted by boiling baryta-water into di-oxy-valeric acid.

**Di-bromo-oxy-valeric acid.**

**Lactone**  $\text{CH}_2\text{Br.CBr.CH}_2\text{CH}_2\text{CO.O}$  or

$\text{CH}_2\text{CBr.CHBr.CH}_2\text{CO.O}$ . [ $78^\circ$ - $81^\circ$ ]. From

(a)-angelico-lactone and bromine. Thick white hygroscopic needles (from  $\text{CS}_2$ ). Water converts it into HBr and bromo-leucic acid (Wolff, A. 229, 264).

**DI-BROMO-PALMITIC ACID**  $\text{C}_{16}\text{H}_{30}\text{Br}_2\text{O}_2$ . [ $29^\circ$ ]. From hypogaeic acid and Br (Schröder, A. 143, 24). Amorphous and insol. water. Alcoholic KOH converts it into bromo-hypogaeic and palmitic acids. Aqueous alkalis form di-oxy-palmitic acid.

**Di-bromo-palmitic acid**  $\text{C}_{16}\text{H}_{30}\text{Br}_2\text{O}_2$ . From gaioic acid and Br. Crystalline; converted by alcoholic KOH into palmitic acid (S.).

**Tri-bromo-palmitic acid**  $\text{C}_{16}\text{H}_{27}\text{Br}_3\text{O}_2$ . [ $39^\circ$ ]. From bromo-hypogaeic acid and Br. Amorphous (S.).

**Tetra-bromo-palmitic acid.**  $\text{C}_{16}\text{H}_{24}\text{Br}_4\text{O}_2$ . Yellow crystals.

**BROMO-PALMITOLIC ACID**  $\text{C}_{16}\text{H}_{31}\text{BrO}_2$ . [ $81^\circ$ ]. From tri-bromo-palmitic acid (v. sup.) and alcoholic KOH (S.).

**BROMO-PENTANE** v. AMYLE BROMIDE.

$\alpha\beta$ -Di-bromo-pentane  $\text{C}_5\text{H}_{10}\text{Br}_2$  i.e.

$\text{CH}_3\text{CH}_2\text{CHBr.CHBr.CH}_3$ . *Amylene bromide*. [ $178^\circ$ ]. S.G.  $\frac{1}{4}$  1.6868. From the corresponding amylenes and Br (Wagner a. Saytzeff, A. 179, 307).

$\alpha\omega$ -Di-bromo-isopentane  $\text{Pr.CH}_2\text{CHBr}_2$ . *Isoamylidene bromide*. [ $170^\circ$ - $180^\circ$ ]. From isovaleric aldehyde and  $\text{PCl}_5\text{Br}_2$  (Bruylants, B. 8, 406). Alcoholic KOH gives  $\text{Pr.CH:CHBr}$  ( $111^\circ$ ) and  $\text{Pr.C:CH}$ .

$\alpha\alpha$ -Di-bromo-pentane  $\text{Pr.CBr}_2\text{CH}_2$ . From methyl propyl ketone and  $\text{PCl}_5\text{Br}_2$  (B.). Split up by distillation into HBr and  $\text{Pr.CBr:CH}_2$  ( $123^\circ$ ).

$\alpha\beta$ -Di-bromo-isopentane

$(\text{CH}_3)_2\text{CBr.CHBr.CH}_3$ . [ $170^\circ$ - $175^\circ$ ]. S.G.  $\frac{1}{4}$  1.6370. M.M. 12.947 at  $12.6^\circ$ . From trimethyl-ethylene and Br (Wurtz, A. Ch. [3] 35, 458; Bauer, B. 2, 149). Converted by water (20 vols.) and  $\text{PbO}$  at  $150^\circ$  into methyl isopropyl ketone (Eltchikoff, J. R. 10, 215).

**Isoamylene dibromide**, formed by combination of Br with isoamylene from crude fusel oil, is a mixture of several of the preceding di-bromo-pentanes (Calours, C. R. 81, 291; Wurtz, A. Ch. [3] 4, 458; A. 123, 202; Reboul, C. R. 58, 1058; A. 133, 84; Bauer, B. 1860, 148; A. 120, 167; Z. 1861, 590; Golovinsky, A. 111, 252; Olevisky, Z. 1861, 674).

**Valerylene dihydrobromide** ( $170^\circ$ - $175^\circ$ ), formed by the union of HBr with crude valerylene is also a mixture of di-bromo-pentanes.

**Tri-bromo-pentane**  $\text{C}_5\text{H}_8\text{Br}_3$ . From bromo-isoamylene and Br.

**Tetra-bromo-pentane**  $\text{C}_5\text{H}_6\text{Br}_4$ . *Valerylene tetrabromide*. [ $-10^\circ$ ]. From crude valerylene and Br (Reboul, A. 132, 119; 135, 372).

**Tetra-bromo-pentane**  $\text{C}_5\text{H}_6\text{Br}_4$ . *Piperylene tetrabromide*. [ $115^\circ$ ]. From piperylene and Br (Hofmann, B. 14, 664). A liquid isomeric is also formed (Magnanimiti, G. 16, 390).

**Tetra-bromo-pentane**  $\text{C}_5\text{H}_6\text{Br}_4$ . *Isoprene tetrabromide*. From isoprene (Tilden, C. N. 46, 120).

**Penta-bromo-pentane**  $\text{C}_5\text{H}_4\text{Br}_5$ . Two bodies of this composition are formed by the action of Br on valerylene in sunlight (R.).

**BROMO-PENTENYL ALCOHOL** *Ethyl ether*  $\text{C}_5\text{H}_9\text{BrO}$  i.e.  $\text{C}_5\text{H}_9\text{Br.OEt}$ . [ $177^\circ$ - $180^\circ$ ]. S.G.  $\frac{1}{4}$  1.23. From tri-bromo-pentane and alcoholic KOH (Reboul, A. 133, 84).

**BROMO-PENTINENE** v. BROMO-VALERYLENE.

**BROMO-PHENANTHRAQUINONE** v. PHENANTHRAQUINONE.

**BROMO-PHENANTHRENE** v. PHENANTHRENE.

**BROMO-DI-PHENIC ACID**

$\text{CO}_2\text{H.C}_6\text{H}_4\text{C}_6\text{H}_4\text{Br.CO}_2\text{H}$ . [ $236^\circ$  uncor.]. Formed, together with its di-bromide, by heating diphenic acid with bromine at  $80^\circ$ - $100^\circ$ . Small white prisms. Sublimes with difficulty. Not volatile with steam. V. sol. alcohol, ether, and acetic acid, sl. sol. benzene, chloroform and  $\text{CS}_2$ , insol. cold water.

**Salts.**— $\text{A}^+\text{Na}$ : white v. sol. amorphous powder.— $\text{A}^+\text{Ba}$  3aq: sparingly soluble needles.— $\text{A}^+\text{Ag}$ : white insol. pp.— $\text{A}^+\text{Cu}$ : sl. sol. amorphous green powder.

*Di-ethyl ether*  $\text{A}^+\text{Et}_2$ : [ $65^\circ$ ]; crystals (Claus a. Erler, B. 19, 3149).

**Bromo-di-phenic-acid-di-bromide**

$\text{C}_{12}\text{H}_8\text{Br}_2(\text{CO}_2\text{H})_2$ . [ $256^\circ$  uncor.]. Formed in small quantity (15 p.c.) by heating diphenic acid (1 mol.) with bromine (2 mols.) for 8 days at  $100^\circ$ . Glistening colourless needles (from hot alcohol). Sl. sol. ordinary solvents. Its alkaline solution decomposes very easily on heating, forming salts of di-bromo-di-phenic acid. It has a very bitter peculiar taste.— $\text{A}^+\text{Na}$ : soluble silky plates (Claus a. Edler, B. 19, 3152).

**Bromo-di-phenic acid**

[4:1]  $\text{C}_6\text{H}_4(\text{COOH})\text{C}_6\text{H}_3\text{Br.COOH}$  [1:4:2]. [ $208^\circ$ ]. Formed by oxidation of the liquid (1,4,1',4',2') mono-bromo-diferyl with  $\text{CrO}_3$  and acetic acid (Carnelley a. Thomson, C. J. 47, 590).

**Di-bromo-di-phenic acid**  $\text{C}_{12}\text{H}_6\text{Br}_2\text{O}_4$ . [ $296^\circ$ ]. From di-bromo-phenanthraquinone,  $\text{K}_2\text{Cr}_2\text{O}_7$ , and  $\text{H}_2\text{SO}_4$ . Geodes of small crystals, v. sl. sol. hot water, insol. alcohol and ether (Ostermayer, B. 7, 1091).

**Di-bromo-di-phenic acid**  $\text{C}_{12}\text{H}_6\text{Br}_2(\text{CO}_2\text{H})_2$ . [ $245^\circ$  uncor.]. Formed by heating di-phenic acid (1 mol.) with bromine (2 mols.) at  $200^\circ$ , or by heating aqueous solutions of salts of mono-bromo-di-phenic-acid-di-bromide. Small glistening needles. Not volatile with steam. Sublimes with difficulty. Sl. sol. benzene, chloroform, acetone,  $\text{CS}_2$ , and hot water, nearly insol. cold water, v. sol. alcohol, ether, and acetic acid.

**Salts.**—The alkaline salts are very soluble amorphous glassy masses.— $\text{A}^+\text{Ag}$ : white amorphous pp.— $\text{A}^+\text{Ca}$  3aq: easily soluble plates.— $\text{A}^+\text{Ph}$ : sl. sol. microcrystalline powder.

*Di-ethyl ether*  $\text{A}^+\text{Et}_2$ : [ $106^\circ$  uncor.]. crystals (Claus a. Edler, B. 19, 3149).

**o-BROMO-PHENOL**  $\text{C}_6\text{H}_4\text{BrO}$  i.e.  $\text{C}_6\text{H}_3\text{Br(OH)}$  [1:2]. ( $195^\circ$ ). From o-bromo-aniline by the diazo-reaction (Fittig a. Mager, B. 8, 362; Körner). Formed in small quantity in brominating phenol (Hübner a. Brenken, B. 6, 171). Oil; volatile with steam. Potash-fusion gives

resorcin.  $\text{HNO}_3$  forms bromo-di-nitro-phenol [118°].

**Methyl ether**  $\text{C}_6\text{H}_4\text{Br.OMe}$ . (223°). From the methyl ether of *o*-anido-phenol by Sandmeyer's reaction (Wallach a. Hensler, *A.* 213, 238).

***m*-Bromo-phenol**  $\text{C}_6\text{H}_4\text{Br(OH)}$  [1:3]. [33°]. (236°). From *m*-bromo-aniline by the diazo-reaction (Körner, *G.* 4, 389; Wurster a. Nölting, *B.* 7, 905; F. a. M.). Crystalline. Potash-fusion gives resorcin.  $\text{HNO}_3$  gives bromo-di-nitro-phenol [92°].

***p*-Bromo-phenol**  $\text{C}_6\text{H}_4\text{Br(OH)}$  [1:4]. [61°]. (237°). S.H. (18°-77°) 3157. S. 1:422 at 15°.

**Formation.**—1. By distilling bromo-*o*-oxybenzoic acid with  $\text{BaCO}_3$  (Cahours, *A. Ch.* [3] 13, 102).—2. By passing air saturated with Br (160 pts.) into cooled phenol (94 pts.) (Körner, *A.* 137, 197).—3. Bromine (160g.) is dissolved in glacial HOAc (200 g.) and added to phenol (94 g.) dissolved in HOAc (300 g.) (Hübner a. Brenken, *B.* 6, 171).—4. From *p*-bromo-aniline by the diazo-reaction (K.; F. a. M.).

**Properties.**—Large crystals (from chloroform); sl. sol. water, v. sol. alcohol. Dimetric;  $a:c=1:1.46$ . Its heat of neutralisation has been determined by Werner (*C. R.* 98, 1333; *Bl.* [2] 46, 281). Nitration gives bromo-di-nitro-phenol [76°]. Potash-fusion gives resorcin.  $\text{SCl}_2$  forms  $\text{S(C}_6\text{H}_3\text{Br.OH)}_2$  [176°] (Tassinari, *G.* 17, 83).

**Methyl ether**  $\text{C}_6\text{H}_4\text{Br.OMe}$ . **Bromo-anisol**. (223° cor.). S.G. 1:441.

**Ethyl ether**  $\text{C}_6\text{H}_4\text{Br.OEt}$ . (233°).

**Isopropyl ether**  $\text{C}_6\text{H}_4\text{Br.OPr}$ . (236°). S.G. 1:981.  $\mu_n$  1:553. From isopropyl phenol and Br (Silva, *Bl.* [2] 13, 27).

**Benzoyl derivative**  $\text{C}_6\text{H}_4\text{Br.OBz}$ . Crystalline.

**Bromo-phenol** (Fourth). (236°-238°) (Fittica, *J. pr.* [2] 23, 176; *B.* 19, 2632; *A. Ch.* [6] 4, 561).

**Preparation.**—Phenol (10 g.), alcohol (40 g.) and amorphous phosphorus (3 g.) are mixed and cooled while bromine (17 g.) is added through a capillary tube. The product is washed with dilute  $\text{Na}_2\text{CO}_3$ , dried and distilled. It contains di-bromo-phenol and the new body. This can only be distilled when in small quantities, in larger masses it undergoes carbonisation.

**Properties.**—Not solid at 10°.

**Nitrat.**—Bromophenol (1 pt.), glacial acetic acid (3 pts.), and  $\text{HNO}_3$  (S.G. 1.4) added gradually form crystals of a molecular compound  $\text{C}_6\text{H}_4\text{Br(NO}_2\text{)OH.C}_6\text{H}_4\text{Br(NO}_2\text{)OH}$  which crystallises from alcohol and melts at [60°-65°]. Fuming  $\text{HNO}_3$  converts this into a bromo-di-nitro-phenol [108°-110°], isomeric with those known. By the action of baryta on the above molecular compound a second such body  $(\text{C}_6\text{H}_3\text{Br(NO}_2\text{)OH})_2\text{C}_6\text{H}_4\text{Br(NO}_2\text{)OH}$  is got.

The existence of four bromo-phenols would be contrary to the general rule that only three isomeric di-derivatives of benzene can be obtained; according to Hand (*A.* 234, 129) the fourth bromo-phenol is merely *p*-bromo-phenol of which the melting-point is lowered by a trace of moisture.

**Di-bromo-phenol**  $\text{C}_6\text{H}_3\text{Br}_2\text{(OH)}$  [1:3:4]. [40°]. S.H. (18°-73°) 2436. S. 194 at 15° (W.).

**Formation.**—1. By distilling di-bromo-salicylic acid with baryta (Cahours, *A.* 52, 329), or

by heating with dilute  $\text{H}_2\text{SO}_4$  at 280° (Peratoner, *G.* 16, 402).—2. By passing bromine-vapour (2 mols.) into cold phenol (1 mol.) (Körner, *A.* 137, 205).

**Properties.**—Crystalline mass, v. sl. sol. water, v. sol. ordinary solvents.  $\text{HNO}_3$  forms picric acid. Its heat of neutralisation has been determined by Werner (*C. R.* 98, 1333). Heated with dilute  $\text{H}_2\text{SO}_4$  in sealed tubes, it is converted into mono- and tri-bromo-phenol (Peratoner, *G.* 16, 403).

**Methyl ether**  $\text{C}_6\text{H}_3\text{Br}_2\text{(OMe)}$ . [59°]. (272°). From di-bromo-phenol,  $\text{NaOH}$ , and  $\text{MeI}$ . Formed also by brominating anisol (C.).

**Nitro-benzoyl derivative**  $\text{C}_6\text{H}_3\text{Br}_2\text{O.CO.C}_6\text{H}_4\text{NO}_2$  [90°-100°]. From benzoyl-phenol by bromination followed by nitration.

**Di-bromo-phenol**  $\text{C}_6\text{H}_3\text{Br}_2\text{(OH)}$  [6:2:1]. [56°]. Formed by distilling tetra-bromo-phenol-phthalic acid with conc.  $\text{H}_2\text{SO}_4$  (Baeyer, *A.* 202, 138). Also from di-bromo-*p*-amido-phenol by displacing  $\text{NH}_2$  by  $\text{H}$  (Möhlau, *B.* 15, 2191). Mass of thin needles (from water).

**Di-bromo-phenol**  $\text{C}_6\text{H}_3\text{Br}_2\text{(OH)}$  [1:3:5]. [76°-5°]. Formed, together with its methyl ether, by heating *s*-tri-bromo-benzene with  $\text{NaOMe}$  (Blau, *M.* 7, 621). Converted by potash-fusion into phloroglucin.

**Methyl ether**  $\text{C}_6\text{H}_3\text{Br}_2\text{(OMe)}$ : [38°].

**Ethyl ether**  $\text{C}_6\text{H}_3\text{Br}_2\text{(OEt)}$ . (268°). Formed by boiling di-bromo-*o*-di-azo-phenol nitrate,  $\text{C}_6\text{H}_3\text{Br}_2\text{(OEt)N}_2\text{NO}_2$ , with water (Möhlau a. Oelmichen, *J. pr.* 132, 482).

**Tri-bromo-phenol**  $\text{C}_6\text{H}_2\text{Br}_3\text{(OH)}$  [2:4:6:1]. [92°] (Wilsing, *A.* 215, 235); [95°] (Körner). S. 1007 at 15° (W.).

**Formation.**—1. From phenol and Br (Laurent, *A. Ch.* [3] 3, 211; Körner, *A.* 137, 208).—2. By distilling tri-bromo-salicylic acid with sand and baryta (C.).—3. By treating indigo with bromine-water.—4. From potassium phenol disulphate and Br (Schmidt, *B.* 11, 852).

**Properties.**—Long silky needles (from dilute alcohol); may be sublimed. V. sl. sol. water, v. sol. alcohol. Its heat of neutralisation has been examined by Werner and Berthelot (*C. R.* 98, 1333; *A. Ch.* [6] 3, 552).

**Reactions.**—1. Nitric acid forms di-bromo-nitro-, bromo-di-nitro-, and tri-nitro-phenol (Armstrong a. Harrow, *C. J.* 29, 476).—2.  $\text{CrO}_3$  and  $\text{HOAc}$  give tetra-bromo-quinone and amorphous insoluble  $\text{C}_6\text{H}_2\text{Br}_4\text{O}_2$  (Benedikt, *A.* 199, 131).—3. Bromine-water forms  $\text{C}_6\text{H}_2\text{Br}_3\text{OBr}$  (?) [118°] which forms yellow plates, insol. water, ether, and alcohol; it exhibits the following reactions: (a) At 130° it splits up into Br and the compound  $\text{C}_6\text{H}_2\text{Br}_3\text{O}$ . (b) Aniline forms tri-bromo-phenol and tri-bromo-aniline. (c) Phenol forms tri-bromo-phenol. (d) It is also reduced to tri-bromo-phenol by boiling alcohol or by Sn and  $\text{HCl}$  (Benedikt, *B.* 12, 1005; *M.* 1, 360; Werner, *Bl.* [2] 43, 373).

**Ethyl ether**  $\text{C}_6\text{H}_2\text{Br}_3\text{OEt}$ . [69°]; prisms (Purgotti, *G.* 16, 526).

**Propionyl derivative**  $\text{C}_6\text{H}_2\text{Br}_3\text{O.C}_2\text{H}_5\text{Br}$ , [65°] (Guareschi a. Daccamo, *B.* 18, 1174).

**Benzoyl derivative**  $\text{C}_6\text{H}_2\text{Br}_3\text{OBr}$ : [82°]; small colourless prisms; soluble in alcohol and ether, nearly insol. water (Daccamo, *B.* 18, 1168).

**Tri-bromo-phenol**

**Ethyl ether**  $C_6H_3Br_3.OEt$ . [73°]. Prepared from tri-bromo-di-azo-phenetol by boiling with water and extracting the product with ether (Möhlau a. Oehmichen, *J. pr.* [2] 24, 484).

**Tetra-bromo-phenol**  $C_6HBr_4.OH$  [2:3:4:6:1]. [120°]. From tri-bromo-phenol and Br at 180° (K.). Formed also by warming  $C_6H_3Br_3.OBr$  (*v. sup.*) with conc.  $H_2SO_4$ . Needles (from alcohol); may be sublimed. Bromine converts it into  $C_6HBr_4.OBr$  [121°] which separates from chloroform in monoclinic crystals and is reduced by boiling alcohol or by Sn and HCl to tetra-bromo-phenol (Benedikt, *M.* 1, 361).

**Penta-bromo-phenol**  $C_6Br_5.OH$ . [225°]. Obtained by heating tri- or tetra-bromo-phenol with excess of Br at 220° for some days (Körner, *A.* 137, 210). Formed also by heating  $C_6H_3Br_3.OBr$  with conc.  $H_2SO_4$  (Benedikt, *M.* 1, 360). Adamantine needles (from  $CS_2$ ); may be sublimed. Conc.  $HNO_3$  forms bromopierin and tetra-bromoquinone.  $PBr_3$  forms  $C_6Br_5$  (Gessner, *B.* 9, 1505; Ruoff, *B.* 10, 1231).

**Hexa-bromo-phenol**  $C_6Br_6.OBr$ . [128°]. Prepared by heating tri-bromo-phenol with excess of bromine in sealed tubes at 220°. Yellow crystals of trimetric system (*a:b:c* = 1:82:114), insol. cold alcohol, but decomposed by boiling into penta-bromo-phenol. On heating with aniline it yields penta-bromo-phenol and tri-bromo-aniline (Benedikt, *M.* 1, 363).

**TETRA-BROMO-*p*-DIPHENYL** *v.* **TETRA-BROMO-DI-OXY-DIPHENYL**.

**TETRA-BROMO-PHENOL-PHTHALEIN** *v.* **PHENOL-PHTHALEIN**.

**BROMO-PHENOL *o*-SULPHONIC ACID**

$C_6H_4Br(OH).SO_3H$ . The K salt is formed by adding Br (1 mol.) to an aqueous solution of potassium phenol *o*-sulphonate. The free acid is very deliquescent.— $KA'$ : pointed needles— $BaA''$ .— $CuA''$  (Senhofer, *A.* 156, 114).

**Bromo-phenol *p*-sulphonic acid**

$C_6H_4Br(OH)(SO_3H)$  [2:1:4]. Formed as in the preceding case (S.), or by passing bromine-vapour into a cold conc. solution of phenol *p*-sulphonic acid (Le Canu, *C. R.* 103, 385). Deliquescent needles (containing 2aq).— $KA'$ .

**Bromo-phenol sulphonic acid.**

**Ethyl derivative**  $C_6H_3Br(OEt)(SO_3H)$ . From potassium phenetol sulphonate and Br (Lippmann, *J.* 1870, 739). Deliquescent mass (containing 4aq).— $KA'$ .

**Bromo-phenol disulphonic acid**

$C_6H_3Br(OH)(SO_3H)_2$  [2:1:4:6]. From an aqueous solution of potassium phenol disulphonic acid (1 mol.) by adding Br (1 mol.) (Armstrong, *C. J.* 25, 865; Schmidt, *B.* 11, 852). Crystalline; *v.* sol. alcohol, *m.* sol. ether. ( $FeCl_3$  gives a red colour.  $HNO_3$  forms bromo-nitro-phenol sulphonic acid, bromo-di-nitro-phenol, and tri-nitro-phenol.— $BaA''$  2aq.— $K_2A''$ .— $PbA''$ .— $Ag_2A''$ ).

**Di-bromo-phenol *o*-sulphonic acid**

$C_6H_3Br_2(OH)(SO_3H)$  [2:4:1:6]. [120°]. Formed by brominating potassium phenol *o*-sulphonate or bromo-phenol *o*-sulphonic acid (Armstrong, *C. J.* 25, 867; Senhofer, *A.* 156, 110; Schmidt, *B.* 11, 855). Concentric needles; deliquescent. The aqueous solution is coloured violet by  $FeCl_3$  and is ppd. by  $Pb(OAc)_2$ .— $HNO_3$  forms di-bromo-*o*-nitro-phenol [117°].  $Ba(C_6H_3Br_2SO_3)_2$ .—

$BaC_6H_3Br_2SO_3$ .— $OdC_6H_3Br_2SO_3$  1½ aq. — $KC_6H_3Br_2SO_3$ .— $K_2C_6H_3Br_2SO_3$ .— $PbC_6H_3Br_2SO_3$ .

**Di-bromo-phenol *p*-sulphonic acid**

$C_6H_3Br_2(OH)(SO_3H)$  [2:6:1:4]. From potassium phenol *p*-sulphonate (1 mol.) and Br (2 mols.) (Senhofer, *A.* 156, 103; Armstrong a. Brown, *C. J.* 25, 857); or by passing bromine-vapour into an aqueous solution of phenol *p*-sulphonic acid (Le Canu, *C. R.* 103, 385). Formed also by diazo-reaction from di-bromo-sulphanilic acid (Schmitt, *A.* 120, 161). Rectangular scales (containing aq). The solution is coloured violet by  $FeCl_3$  but is not ppd. by  $Pb(OAc)_2$ .—

$KC_6H_3Br_2SO_3$  aq.— $K_2C_6H_3Br_2SO_3$  2aq.—

$Ba(C_6H_3Br_2SO_3)_2$  2aq.— $BaC_6H_3Br_2SO_3$  4aq.

**BROMO-PHENOXY-ACETIC ACID** *v.* **Bromo-phenyl derivative of GLYCOLIC ACID**.

**BROMO-PHENOXY-PROPIONIC ACID** *v.*

**Bromo-phenyl derivative of LACTIC ACID**.

***o*-BROMO-DIPHENYL**  $C_6H_4Br$  *ie.*

$C_6H_5.C_6H_4Br$  [1:2]. (258°). Formed by decomposing *o*-diazo-diphenyl perbromide with alcohol (Schultz, Schmidt, a. Strasser, *A.* 207, 353). Oil, smelling of oranges; oxidised by  $CrO_3$  to *o*-bromo-benzoic acid.

***p*-Bromo-diphenyl**  $C_6H_5.C_6H_4Br$  [1:4]. [89°] (310° i. V.). Formed by adding Br to a solution of diphenyl in  $CS_2$ . Laminæ; *v.* sol. hot alcohol and HOAc, *v.* e. sol. ether. Smells like oranges. Chromic acid oxidises it to *p*-bromo-benzoic acid (Schultz, *A.* 174, 207).

***pp*-Di-bromo-diphenyl** [4:1]  $C_6H_4Br.C_6H_4Br$  [1:4]. [164°] (G.; F.); [162°] (C. a. T.). (c. 358°). Formed by heating diphenyl dissolved in  $CS_2$  with bromine at 100° (Fittig, *A.* 132, 204; Carnelley a. Thomson, *C. J.* 17, 588). Also from benzidine by the diazo-reaction (Griess, *Pr.* 13, 383). Prisms and octahedra (C. a. T.); *v.* sl. sol. hot alcohol, slightly volatile with steam. Smells like oranges. Oxidised by  $CrO_3$  to *p*-bromo-benzoic acid.

**Tri-bromo-diphenyl** [4:1]  $C_6H_4Br.C_6H_3Br_2$ . Formed by the action of bromine on a mixture of diphenyl and *p*-tolyl-benzene (Carnelley a. Thomson, *C. J.* 17, 587). Colourless silky needles, sl. sol. alcohol, not volatile with steam.  $CrO_3$  in HOAc gives *p*-bromo-benzoic acid.

**DI-BROMO-DI-PHENYL-ACETAMIDINE**

$C_6H_4Br_2.N_2$  *ie.*  $CH_3C(NHC_6H_4Br)_2NC_6H_4Br$ . From *p*-bromo-aniline, HOAc, and  $PCl_5$  (Dennstedt, *B.* 13, 233).— $BTiCl_3$ .— $B''H_2PtCl_6$ .

***o*-BROMO-PHENYL-ACETIC ACID**  $C_6H_4BrO_2$  *ie.* [2:1]  $C_6H_4Br.CH_2.CO_2H$  [104°]. From phenyl-acetic acid, bromine and HgO. Separated from the *p*-compound by its more soluble barium salt (Bedson, *C. J.* 37, 95). Flat needles (from water). Monoclinic tablets (from glacial acetic acid).—*a:b:c* = 1:657:1767;  $\alpha$  = 99° 44'.  $KMnO_4$  oxidises it to *o*-bromo-benzoic acid.— $CaA''$ .— $AgA''$ .

**Nitrile**  $C_6H_4Br.CH_2.CN$ . Oil (Jackson a. White, *Am.* 2, 316).

***m*-Bromo-phenyl-acetic acid**

[3:1]  $C_6H_4Br.CH_2.CO_2H$ . [97°] (J. a. W.); [100°] (G.). From (3, 4, 1)-bromo-amido-phenyl-acetic acid by removing  $NH_2$  (Gabriel, *B.* 15, 841).

**Nitrile**  $C_6H_4Br.CH_2.CN$ . Oil (Jackson a. White, *P. Am.* A. 16, 256).

***p*-Bromo-phenyl-acetic acid**

[4:1]  $C_6H_4Br.CH_2.CO_2H$ . [115°]. Prepared by treating phenyl-acetic acid with bromine and

HgO (Bedson, *C. J.* 37, 94).—Long flat needles; may be sublimed. Oxidation gives *p*-bromobenzoic acid.

Salts.— $\text{AgA}'$ .— $\text{NH}_4\text{A}'$ .— $\text{BaA}'_2$ .— $\text{CaA}'_2$ .— $\text{CuA}'_2$ .

**Nitrile**  $\text{C}_6\text{H}_5\text{Br}.\text{CH}_2.\text{CN}$ . [47°]. Prepared by boiling *p*-bromo-benzyl bromide with alcoholic KCN (Loring Jackson & Lowery, *B.* 10, 1210; *Am. S.* 248).

**$\alpha$ -Bromo-phenyl-acetic acid**  $\text{C}_6\text{H}_5.\text{CHBr}.\text{CO}_2\text{H}$ . [84°]. From mandelic acid and conc.  $\text{HBr}$  at 130° (Glaser & Radziszewski, *Z.* 1868, 142).

Formed also by brominating phenyl-acetic acid at 150° (Radziszewski, *B.* 2, 208). Monoclinic crystals (from  $\text{CS}_2$ ). Reduced by sodium-amalgam to phenyl-acetic acid. Boiling  $\text{NaOH}$  gives mandelic acid  $\text{C}_6\text{H}_5.\text{CH}(\text{OH}).\text{CO}_2\text{H}$ . Alcoholic KOH gives  $\text{C}_6\text{H}_5.\text{CH}(\text{OEt}).\text{CO}_2\text{H}$ . The ethyl ether is converted by alcoholic KCy into  $\text{CO}_2\text{Et}.\text{CHPh}.\text{CHPh}.\text{CO}_2\text{Et}$ , and by Na into  $\text{CO}_2\text{Et}.\text{CPh}:\text{CPh}.\text{CO}_2\text{Et}$ .

**Nitrile**  $\text{C}_6\text{H}_5.\text{CHBr}.\text{CN}$ . Is the chief product of the action of bromine on benzyl cyanide at 120°. Sol. alcohol and ether. On heating to 170° or with alcoholic KCN it gives di-cyano-stilbene. With an excess of KCN di-cyano-di-benzyl is also formed. On boiling with alcoholic KOH it gives stilbene-di-carboxylic acid (Reimer, *B.* 14, 1797).

**Hydrobromide of the Nitrile**  $\text{C}_6\text{H}_5.\text{CHBr}.\text{CBr}.\text{NH}_2$ . *Phenyl-bromo-acetimidobromide*. Formed together with the nitrile by the action of bromine on benzyl cyanide at 120°; the yield being 15 p.c. Colourless crystals. Bitter taste. Its vapour attacks the eyes. V. sl. sol. all solvents, most easily in boiling acetic acid. Decomposed by water and alcohol.—HCl at 150° converts it into  $\alpha$ -bromo-phenyl-acetic acid (?) and  $\text{NH}_3$ . Dilute HCl at 150° converts it into  $\text{NH}_3$ , mandelic acid ( $\text{C}_6\text{H}_5.\text{CH}(\text{OH}).\text{CO}_2\text{H}$ ), and HBr (Reimer, *B.* 14, 1797).

**$\alpha$ -Bromo-di-phenyl-acetic acid**  $(\text{C}_6\text{H}_5)_2\text{CBr}.\text{CO}_2\text{H}$ . From diphenyl-acetic acid and Br at 150°. Converted by boiling water into benzoic acid  $\text{CPh}_2(\text{OH}).\text{CO}_2\text{H}$  (Symons & Zincke, *A.* 171, 131).

**Di-bromo-phenyl-acetic acid**  $\text{C}_6\text{H}_5.\text{Br}_2.\text{CH}_2.\text{CO}_2\text{H}$ . [115°]. Formed by action of sunlight on mixture of *o*- and *p*-bromo-phenyl-acetic acids and Br. Purified by conversion into the methyl ether, distillation and saponification (Bedson, *C. J.* 37, 96). White needles.— $\text{AgA}'$ .

**BROMO-PHENYL-ACRYLIC ACID** *v.* BROMO-CINNAMIC ACID and BROMO-ATROPIC ACID.

**DI-BROMO-DI-PHENYL-ALLOPHANIC ACID**  $\text{C}_6\text{H}_5.\text{N}(\text{N}.\text{Br}.\text{O})_2$  *i.e.*  $\text{C}_6\text{H}_5.\text{Br}.\text{NH}.\text{CO}.\text{N}(\text{C}_6\text{H}_5.\text{Br}).\text{CO}_2\text{H}$ .

*Ethyl ether*. [153°]. The compound which is formed from *p*-bromophenyldicyanate by long boiling with alcohol is probably this ether. Fine white needles. Sol. alcohol and ether. By continued action of alcohol it is converted into *p*-bromo-phenyl-carbamic ether (Dennstedt, *B.* 13, 229).

***p*-BROMO-PHENYL-AMIDO-ACETIC ACID**  $\text{CH}_2(\text{NH}.\text{C}_6\text{H}_4.\text{Br}).\text{CO}_2\text{H}$ . *Bromo-phenyl-glycolic*. [98°]. Colourless crystals. V. a. sol. alcohol, ether and hot water. Forms a light-green copper salt. Prepared by the action of chloro-acetic acid on *p*-chloroaniline.

VOL. I.

*Ethyl ether A'Et*: [96°]; white needles. Insol. water, sol. alcohol and ether.

***p*-Bromoanilide**  $\text{CH}_2(\text{NH}.\text{C}_6\text{H}_4.\text{Br}).\text{CONH}(\text{C}_6\text{H}_4.\text{Br})$ : [155°–160°]; white microscopic crystals. Sublimes at about 145°. Sl. sol. hot water, v. sol. alcohol and ether (Dennstedt, *B.* 13, 236).

**Di-bromo-di-phenyl-amido-acetic acid**. **Nitrile**  $\text{C}_6\text{H}_5.\text{Br}.\text{NH}.\text{CHPh}.\text{CN}$ . [92°]. From di-phenyl-amido-acetic acid and Br (Tiemann & Pielst, *B.* 15, 2032). Yellow rhombohedra (from alcohol).

**Tri-bromo-phenyl-amido-acetic acid**  $\text{C}_6\text{H}_5.\text{Br}_3.\text{NH}.\text{CH}_2.\text{CO}_2\text{H}$ . Formed by adding bromine-water to an aqueous solution of phenyl-amido-acetic acid. Minute needles (from  $\text{HOAc}$ ). Insol. water, acids and alkalis (Schwebel, *B.* 11, 1131).

**BROMO-PHENYL-AMIDO-CHLORO-NAPHTHOQUINONE** *v.* CHLORO-NAPHTHOQUINONE-BROMANILIDE.

**$\alpha$ -BROMO-PHENYL- $\beta$ -AMIDO-CROTONIC ACID**  $\text{CH}_2.\text{C}(\text{NHPh}).\text{CBr}.\text{CO}_2\text{H}$ . *Anil-bromo-aceto-acetic acid*. [138°]. Formed by bromination of phenyl- $\beta$ -amido-crotonic acid (anilacetacetic acid) dissolved in chloroform. Pearly plates, v. sol. hot alcohol, sl. sol. water, chloroform and ether. By cold  $\text{H}_2\text{SO}_4$  it is condensed to (*Py.* 2:1:3)-bromo-oxy-methyl-quinoline (Knorr, *B.* 17, 2874).

**BROMO-PHENYL-AMIDO-( $\alpha$ )-NAPHTHO-QUINONE** *v.* ( $\alpha$ )-NAPHTHOQUINONE-BROMANILIDE.

**TRI-BROMO-PHENYL-AMIDO-PROPIONITRILE**  $\text{C}_6\text{H}_5.\text{Br}_3.\text{NH}.\text{CHMe}.\text{CN}$ . [130°]. From phenyl- $\alpha$ -amido-propionitrile and Br. Needles (Stephan, *C. C.* 1886, 470).

***p*-BROMO-PHENYL-(*Py.* 3)-AMIDO-QUINOLINE**  $\text{CH}:\text{CH}$

**INE**  $\text{C}_6\text{H}_5\text{K}$   $\begin{matrix} \text{CH}:\text{CH} \\ \text{N}:\text{C}(\text{NH}.\text{C}_6\text{H}_4.\text{NO}_2) \end{matrix}$  [146°]. Silvery scales. Formed by heating (*Py.* 3)-chloro-quinoline with *p*-bromaniline (Friedländer & Weinberg, *B.* 1, 1533).

**DI-BROMO-DI-PHENYL-AMINE**  $\text{HN}(\text{C}_6\text{H}_4.\text{Br})_2$ . [107°]. Prisms. Sol. alcohol and acetic acid. The benzoyl derivative is formed by bromination of benzoyl-di-phenyl-amine.

*Benzoyl derivative*  $\text{BzN}(\text{C}_6\text{H}_4.\text{Br})_2$ . [142°]. Colourless plates. Soluble in alcohol and acetic acid (Lellmann, *B.* 15, 830).

**Tetra-bromo-di-phenyl-amine**  $\text{NH}(\text{C}_6\text{H}_4.\text{Br})_2$ . [182°]. Formed by treating an alcoholic solution of di-phenyl-amine with Br. Needles (Hofmann, *A.* 132, 166; Gmelin, *B.* 8, 925).

*Acetyl derivative*  $\text{NAc}(\text{C}_6\text{H}_4.\text{Br})_2$ . [158°].

**Hexa-bromo-di-phenyl-amine**  $\text{NH}(\text{C}_6\text{H}_4.\text{Br})_2$ . [218°]. Formed, together with the preceding, by adding Br to a solution of di-phenyl-amine in  $\text{HOAc}$  (G.). Reduced by sodium-amalgam to di-phenyl-amine.

**Octo-bromo-di-phenyl-amine**  $\text{NH}(\text{C}_6\text{H}_4.\text{Br})_2$ . [c. 304°]. From di-phenyl-amine, Br, and I at 360°. Prisms (from  $\text{CHCl}_3$ ) (Gessner, *B.* 9, 1511).

**Deca-bromo-di-phenyl-amine**  $\text{NH}(\text{C}_6\text{H}_4.\text{Br})_2$ . From di-phenyl-amine, Br, and I at 360°. Needles (from  $\text{CHCl}_3$ ). Not melted at 310°.

**BROMO-PHENYL-BENZENE** *v.* BROMO-DI-PHENYL.

**Bromo-tri-phenyl-benzene**  $\text{C}_6\text{H}_5.\text{Br}$ . [104°]. From Br and tri-phenyl-benzene in  $\text{CS}_2$ . Needles (from alcohol) (Berthold & Engler, *B.* 7, 1123).

R R

**BROMO-PHENYL-BENZOIC ACID** *v.***BROMO-DIPHENYL-CARBAMIC ACID.****BROMO-PHENYL BENZYL OXIDE** $C_6H_5Br.O.CH_2.C_6H_5$ . [59°]. From phenyl benzyl oxide, Br, and  $HgO$ . Needles (Sintenis, A. 161, 335).**DI-*p*-BROMO-DI-PHENYL-BIURET** $C_{14}H_{11}O_2Br_2N_4$  *i.e.*  $(C_6H_5Br.NH.CO)_2NH$ . Prepared by the action of alcoholic  $NH_3$  on *p*-bromo-phenyl-dicyanate (Dennstedt, B. 13, 230). Sl. sol. alcohol and ether, inf. sol. water. Begins to sublime at about 240°.***γ*-BROMO-*γ*-PHENYL-BUTYRIC ACID** $Ph.CHBr.CH_2.CH_2.CO_2H$ . [69°]. From *γ*-phenyl-iso-crotonic acid and conc.  $HBr$  at 0°. Crystals (from  $CS_2$ ) (Jayne, A. 216, 102). By boiling with water or treatment with aqueous  $Na_2CO_3$  it is converted into the lactone of *γ*-oxy-*γ*-phenyl-butyric acid (*q. v.*).***β*-Di-bromo-*γ*-phenyl-butyric acid** $Ph.CHBr.CHBr.CH_2.CO_2H$ . [138°]. From phenyl-iso-crotonic acid in  $CS_2$  by Br at 0° (Jayne, A. 216, 107). Crusts of small white crystals. Sodium amalgam converts it into sodium *γ*-oxy-*γ*-phenyl-butyrate.***exo*-Di-bromo-*β*-phenyl-isobutyric acid** $C_6H_5.CHBr.CBrMe.CO_2H$  (?) [135°]. From phenyl-methacrylic acid and Br (Conrad a. Hodgkinson, A. 193, 312).***p*-BROMO-PHENYL-CARBAMIC ACID***Methyl ether*  $C_6H_4Br.NH.CO_2Me$ . [124°]. From *p*-bromo-phenyl cyanate and  $MeOH$ . Needles (Dennstedt, B. 13, 229).*Ethyl ether*  $C_6H_4Br.NH.CO_2Et$ . *Bromo-carbanilic ether*. [81°] (B.); [85°] (D.). From  $PhNH.CO_2Et$  and bromine-water (Behrend, A. 233, 7) or from *p*-bromo-aniline and  $ClCO_2Et$ . Needles (from benzoline). Boiling alcoholic  $KOH$  gives  $K_2CO_3$  and *p*-bromo-aniline.*Di-bromo-phenyl-carbamic acid. Methyl ether* [4:2:1]  $C_6H_3Br_2.NH.CO_2Me$ . [97°]. Formed by brominating methyl phenyl-carbamate (Hentschel, J. pr. [2] 34, 423). Needles (from alcohol). Warm  $H_2SO_4$  gives  $CO_2$  and di-bromo-aniline.**Hexa-bromo-di-phenyl-carbamie ether**  $(C_6H_2Br_6).N.CO_2Et$ . *Hexa-bromo-di-phenylamine urethane*. [184°]. Formed by bromination of di-phenyl-carbamie ether dissolved in acetic acid (Hager, B. 18, 2577). Long greenish-brown needles. Sol. acetic acid, nearly insol. alcohol.***p*-BROMO-PHENYL-CARBAMINE DI-CHLORIDE**  $C_6H_4Br.NCl_2.COCl$ . (56°). From *p*-bromo-phenyl carbimide and  $Cl_2$ . Yellowish liquid (Dennstedt, B. 13, 232).**DI-BROMO-DI-PHENYL-CARBINOL** $C_{12}H_9Br_2O$ . [163°]. *Di-bromo-benzhydrol*. From di-phenyl-carbinol and Br. Minute needles (from alcohol). Reduced by sodium-amalgam to di-phenyl-carbinol (Linnemann, A. 133, 6).**DI-BROMO-PHENYL CARBONATE** $(C_6H_4Br_2).CO_2$ . [166°]. Silky needles; formed by brominating phenyl carbonate (Löwenberg, C. C. 1886, 390).**BROMO-DIPHENYL CARBOXYLIC ACID.**[4:1]  $C_6H_4Br.C_6H_4.CO_2H$  [1:4]. [194°]. From *p*-bromo-phenyl-toluene [30°] and  $CrO_3$  in  $HOAc$  (Carnelley a. Thomson, C. J. 51, 88). V. sol. ether, sl. sol. alcohol.**Di-bromo-diphenyl carboxylic acid** $C_{12}H_7Br_2.CO_2H$  [4':1':1:2or3:4]. *Di-bromo-**phenyl-benzoic acid*. [204°]. From di-bromo-*p*-tolyl-benzene [115°] by oxidising with  $CrO_3$  in  $HOAc$ . Needle-shaped prisms (from alcohol), sl. sol. alcohol (Carnelley a. Thomson, C. J. 47, 589).**Di-bromo-diphenyl *p*-carboxylic acid** $C_{12}H_7Br_2.C_6H_4Br.CO_2H$  [4':1':1:2or3:4]. [232°]. Formed by oxidising di-bromo-tolyl-benzene [150°] (C. a. T., C. J. 51, 90).*Di-bromo-diphenyl carboxylic acid* [212°] has been obtained from (8)-di-bromo-fluorene-ketone [197°] by potash-fusion (Holm, B. 16, 1081).— $BaA'$ .***p*-BROMO-PHENYL CYANATE** $OC.N.C_6H_4Br$  [1:4]. [39°]. (226°). V. sol. ether. Prepared by distilling bromo-phenyl-carbamic ether with  $P_2O_5$  (Dennstedt, B. 13, 228).***p*-BROMO-PHENYL DI-CYANATE** $C_{11}H_8N_2O_2Br_2$ . [199°]. Small plates. Sl. sol. ether. Prepared by the action of a small quantity of tri-ethyl-phosphine on bromo-phenyl-cyanate heated to 100°. By long boiling with absolute alcohol it gives an acid of melting-point [153°] and formula  $C_{10}H_7O_2N_2Br_2$ , which is probably ethyl di-bromo-phenyl-allophanate (Dennstedt, B. 13, 229).**BROMO-PHENYL-CYSTEINE**  $C_6H_4Br.NSO_2$ *i.e.*  $C_6H_4Br.S.CMe(NH_2).CO_2H$ . *p-Bromo-α-amido-thio-lactic acid*. [181°]. Formed by boiling bromo-phenyl-mercapturic acid with conc.  $HCl$ . Needles (from dilute alcohol); v. sl. sol. water, v. sl. sol. alcohol, v. sol. dilute  $HCl$ . Boiling alkalis slowly separate *p*-bromo-phenyl mercaptan and form pyruvic acid. Sodium-amalgam forms  $NH_3$ , lactic acid, and  $C_6H_4Br.SH$ . Acetic anhydride on warming gives an anhydride  $C_6H_4Br.S.CMe \begin{smallmatrix} NH \\ <CO \end{smallmatrix}$  [153°]bromo-phenyl-cystein, but in presence of benzene it forms bromo-phenyl-mercapturic acid  $C_6H_4Br.S.CMe(NHAc).CO_2H$ . Potassium cyanate forms  $C_6H_4Br.S.CMe(NH.CO.NH_2).CO_2H$ .Salts.— $CuA'$ .— $HA'HCl$  (Baumann a. Preusse, H. 5, 315; B. 18, 258).**BROMO-*o*-PHENYLENE-DIAMINE** $C_6H_3Br(NH_2)_2$  [4:1:2]. [63°]. From (1,3,4)- or (6,3,4)-bromo-nitro-aniline, tin, and  $HCl$  (Hübner, A. 210, 359; Wurster, B. 6, 1544; Remmers, B. 7, 347). Needles; v. sol. water. Sodium-amalgam reduces it to *o*-phenylene diamine.Salts.— $B'HCl$ .— $B''H_2SO_4$ .**Di-bromo-*m*-phenylene-diamine** $C_6H_3Br_2(NH_2)_2$ . Dark brown pp. formed by adding bromine-water to an aqueous solution of *p*-phenylene-diamine hydrochloride; may be crystallised from alcohol (Holleman, Z. 1865, 555).**BROMO-DIPHENYLENE KETONE** $C_{12}H_7BrO$  *i.e.*  $\begin{smallmatrix} C_6H_5 \\ | \\ C_6H_4Br \end{smallmatrix} > CO$ . [104°]. From bromo-fluorene and  $CrO_3$  (Hodgkinson a. Matthews, C. J. 43, 165). Dark yellow needles.*Bromo-diphenylene ketone*  $C_{13}H_7BrO$ . [122° uncor.]. Formed by distilling bromo-diphenic acid with lime. Yellow plates. V. sol. benzene, ether, and hot alcohol, nearly insol. water. Sublimes readily in felted needles. By distillation with zinc-dust it gives fluorene (Claus a. Erler, B. 19, 3155).

(a)-Di-bromo-diphenylene-ketone  $C_{12}H_8Br_2CO$ . [148°]. Formed by oxidation of di-bromo-fluorene [166°] with  $CrO_3$  dissolved in acetic acid (Holm, *B.* 16, 1081). Long yellow needles. V. sol. ether and benzene.

(s)-Di-bromo-diphenylene ketone  $C_{12}H_8Br_2CO$ . [198°]. From (a)-di-bromo-fluorene [165°] by  $CrO_3$  in slight excess and  $HOAc$  (Hodgkinson a. Matthews, *C. J.* 43, 165; Holm). Yellow needles, sol. alcohol, ether, and benzene. Potash-fusion gives rise to di-bromo-diphenyl-carboxylic acid.

Di-bromo-diphenylene-ketone  $C_{12}H_8Br_2CO$ . [138° uncor.]. Formed by distilling di-bromo-di-phenic acid with lime. Thin yellow plates or long thin needles. Readily sublimable (Claus a. Erler, *B.* 19, 3156).

DI-BROMO-DI-PHENYLENE KETONE OXIDE  $C_{12}H_6Br_2O_2$  [210°-213°]. From diphenylene ketone oxide and bromine at 180° (A. G. Perkin, *C. J.* 43, 193). Long needles (from alcohol). Combines with bromine forming an unstable addition product.

BROMO-DIPHENYLENE-METHANE v. BROMO-FLUORENE.

DI-BROMO-PHENYLENE-(a)-NAPHTHYLENE-OXIDE  $C_{16}H_{12}Br_2O$  [284°]. Yellowish white needles. Sl. sol. benzene. Prepared by bromination of phenylene-(a)-naphthylene-oxide (Arx, *B.* 13, 1727).

BROMO-PHENYLENE OXIDE  $C_{12}H_8BrO$ . [195°]. From phenylene oxide and Br at 100°. Needles (from alcohol) (Märker, *A.* 124, 250).

Di-bromo-diphenylene oxide  $C_{12}H_8Br_2O$ . [185°]. From Br and diphenylene oxide in  $CS_2$ . Laminæ (from alcohol) (Hoffmeier, *A.* 159, 211).

DI-BROMO-DIPHENYLENE-PHENYL-METHANE  $C_{15}H_{12}Br_2$ . [182°]. From Br and the hydrocarbon in  $HOAc$  (Behr, *B.* 5, 971).

Tri-bromo-diphenylene-phenyl-methane  $C_{15}H_9Br_3$ . [167°-171°] (B.).

BROMO-PHENYL-ETHANE v. BROMO-ETHYLBENZENE.

p-Bromo-di-phenyl-ethane  $C_{14}H_{13}Br$  i.e.  $C_6H_5CH_2CH_2C_6H_5$  [1:4]. Bromo-dibenzyl. S.G. 21.40. From s-di-phenyl-ethane, Br, and water (Fittig a. Stelling, *A.* 137, 266). Oil; boils above 320°.

pp-Di-bromo-di-phenyl-ethane  $C_{14}H_{11}Br_2$  i.e. [4:1]  $C_6H_4BrCH_2CH_2C_6H_4Br$  [1:4]. [115°]. From s-di-phenyl-ethane, water, and Br (F. a. S.). Needles (from alcohol).  $CrO_3$  gives p-bromobenzoic acid.

Exo-di-bromo-s-di-phenyl-ethane  $C_{14}H_{11}Br_2$  CHBr.CHBBr.C<sub>6</sub>H<sub>5</sub>. [237°] (Z.); [235°] (K.). Stilbene dibromide. Di-bromo-dibenzyl.

Formation.—1. From stilbene and Br (Limpriat a. Schwanert, *A.* 145, 336).—2. From dibenzyl and dry Br (Marquardt, *A.* 151, 364).—3. From hydrobenzoin and PBr<sub>3</sub> (Zincke, *A.* 198, 127).

Properties.—Silky needles. Decomposes at 285° (Kade, *J. pr.* 127, 465). V. sl. sol. boiling alcohol, m. sol. boiling xylene. Alcoholic KOH gives  $C_6H_5CH:CHBr.C_6H_5$  and  $C_6H_5C:C(C_6H_5)_2$ . Converted by benzene and  $AlCl_3$  into s-tetra-phenyl-ethane some tri-phenyl-methane being also formed (Anschütz, *A.* 235, 207).

Tri-bromo-s-di-phenyl-ethane  $C_{14}H_9Br_3$ . From s-di-phenyl-ethane, water, and Br (F. a. S.).

Nacreous laminæ, v. sl. sol. alcohol; decomposes at 170°.

Tri-bromo-s-di-phenyl-ethane  $C_{14}H_9Br_3$ . [207°-211°]. From s-di-phenyl-ethane and dry Br (M.).

Tri-bromo-s-di-phenyl-ethane  $C_{14}H_9Br_3$ . Bromo-stilbene dibromide. [100°]. From bromo-s-diphenyl-ethylene and Br (L. a. S.). Needles (from alcohol). Decomposed by distillation into 11Br, PhCBr:CHBr.Ph, and PhC:CHPh. Alcoholic KOH gives PhC:CHPh.

Tri-bromo-u-di-phenyl-ethane  $(C_6H_5)_3CH.CBr_2$ . [89°]. From bromal (1 mol.), benzene (2 mols.) and conc.  $H_2SO_4$  (Goldschmidt, *B.* 6, 985). Monoclinic prisms (from ether). Alcoholic KOH gives 11Br and di-bromo-di-phenyl-ethylene.

Hexa-bromo-s-di-phenyl-ethylene  $C_{14}H_2Br_6$ . From s-di-phenyl-ethane and excess of Br. Hard prisms (from benzene) (F. a. S.).

BROMO-PHENYL-ETHYL-AMINE v. BROMO-AMIDO-PHENYL-ETHANE.

BROMO-u-DI-PHENYL-ETHYLENE  $C_{14}H_{11}Br$  i.e.  $(C_6H_5)_2C:CHBr$ . [50°] (H.); [40°] (A.). (c. 170°) at 11 mm. (A.); (above 300°) (H.). Formed by warming the di-bromide of u-di-phenyl ethylene (Hepp, *B.* 7, 1410; Anschütz, *A.* 235, 160). Prisms; sl. sol. cold alcohol.

Bromo-s-di-phenyl-ethylene  $C_{14}H_{11}Br$ . Bromo-stilbene. [25°]. From stilbene di-bromide by distillation or treatment with alcoholic KOH. Prisms.  $AgOAc$  gives PhC(OAc):CHPh (Limpriat a. Schwanert, *A.* 145, 340; 155, 72).

Di-bromo-u-di-phenyl-ethylene  $(C_6H_5)_2C:CHBr_2$ . [83°]. (above 300°). From  $C_{14}H_{11}Br_2$  and alcoholic KOH (Goldschmidt, *B.* 6, 985). Needles (from alcohol-ether).

Di-bromo-s-di-phenyl-ethylene  $C_{14}H_9Br_2$ . Toluene di-bromide. [208°]. Leaflets. Prepared by the action of bromine on toluene. An isomeride [61°] is also formed in small quantity (Limpriat a. Schwanert, *A.* 145, 318; Liebermann a. Homeyer, *B.* 12, 1974). Converted by benzene and  $AlCl_3$  in presence of  $CS_2$  into s-tetra-phenyl-ethane (Anschütz, *A.* 235, 209).

BROMO-PHENYL-GLYCOCOLL v. BROMO-PHENYL-AMIDO-ACETIC ACID.

DI-BROMO-DI-PHENYL-GUANIDINE

$C_{14}H_{11}Br_2N_3$ . From di-phenyl-guanidine hydrochloride, water, and Br (Hofmann, *A.* 67, 148). Scales (from alcohol).— $BHCl$ .— $B'HI$ . $PtCl_5$ .

Tri-bromo-tri-phenyl-guanidino  $C_{18}H_{11}N_3Br_3Cl$  i.e.  $(C_6H_5)_3N:CN(C_6H_5)_3Br$ . White amorphous powder. Prepared by the action of p-bromaniline on iso-cyan-p-bromophenyl-chloride.— $BHCl$ : white crystals, easily soluble in alcohol and ether.— $(B'HI)PtCl_5$ : light yellow plates (Dannstedt, *B.* 13, 232).

p-BROMO-PHENYL-MERCAPTAN

$2,4,6,8,10$ . [75°]. [231°]. From p-bromobenzene sulphochloride, tin, and  $HCl$  (Hübner a. Alsberg, *A.* 156, 327). Formed also by boiling bromo-phenyl-cysteine or bromo-phenyl-mercaptopuric acid with  $NaOH$ aq. (Baumann a. Preusse, *B.* 12, 806; *H.* 5, 519). Laminæ (from alcohol); volatile with steam; sl. sol. hot water. Conc.  $H_2SO_4$  at 120° forms a green solution, turning blue. Sodium-amalgam forms phenyl-mercaptan. Chloral forms a compound

[72°]. HCl passed into a mixture of *p*-bromophenyl mercaptan and benzoic aldehyde forms di-*p*-bromo-di-phenyl-di-thio-benzaldehyde  $C_6H_4BrCH(S.C_6H_4Br)_2$  [80°] (Baumann, *B.* 18, 885). HCl and acetone form di-bromo-di-thio-dimethyl ketate  $(CH_3)_2C(S.C_6H_4Br)_2$  [90°].

***p*-BROMO-PHENYL-MERCAPTURIC ACID**  $C_{11}H_9BrNSO_3$ , i.e.  $C_6H_4BrS.CMe(NHAc).CO_2H$ . *Acetyl-bromo-phenyl-amido-thio-lactic acid*. [153°]. S. 1.4 at 100°. Occurs in the urine of animals which have taken bromo-benzene. Formed also by treating bromic phenyl-cysteine with benzene and  $Ac_2O$  (Baumann a. Preusse, *B.* 12, 806, *II.* 5, 309; Baumann, *B.* 15, 1732; Jaffe, *B.* 12, 1092). Needles; insol. cold water, sol. hot water and alcohol. Levorotatory in alcoholic solution, dextrorotatory in alkaline solution. Boiling aqueous NaOH gives *p*-bromophenyl mercaptan,  $NH_3$ , HOAc, and pyruvic acid. Boiling conc. HClAq or dilute  $H_2SO_4$  gives acetic acid and bromo-phenyl-cysteine. Conc.  $H_2SO_4$  gives a blue solution.

Salts.— $BaA'_2$  2aq: S. 2 at 15°.— $MgA'_2$  9aq.— $NH_4A'$ : S. 3 at 15°.

**BROMO-DI-PHENYL-METHANE**  $C_{13}H_{11}Br$  i.e.  $CHPh_2Br$ . [45°]. From di-phenyl-methane (1 mol.) and Br (1 mol.) at 150° (Friedel a. Baisohn, *Bl.* [2] 33, 339, 587). Crystals, v. e. sol. benzene. Water at 100° forms di-phenyl-carbinol and its anhydride. Boiling alcohol forms  $CHPh_2.OEt$ . Conc.  $NH_4Aq$  gives  $CHPh_2.NH_2$ .

Di-bromo-di-phenyl-methane  $CPh_2Br_2$ . From di-phenyl-methane (1 mol.) and Br (2 mols.) at 150°. Liquid. Water at 150° converts it into benzophenone. Decomposed on distillation giving tetra-phenyl-ethylene. Sodium and water form tetra-phenyl-ethane.

**Bromo-tri-phenyl-methane**  $C_{18}H_{15}Br$  i.e.  $Ph_3CBr$ . [152°]. Obtained by brominating tri-phenyl-methane in sunlight or at 150° (Allen a. Kollieker, *A.* 227, 107; Henderso. *C. J.* 51, 224; Schwarz, *B.* 14, 1520). Yellow hexagonal rhombohedra (from  $CS_2$ )  $a:c = 1:784$  (Hintze, *Z. K.* 9, 536). Decomposed above 200° into  $HBr$  and phenylene-di-phenyl-methane. Successive treatment with boiling HOAc and water forms tri-phenyl-carbinol.  $NH_3$  forms  $Ph_3CNH_2$ . KCy gives  $Ph_3C.Cy$ . Potassium sulphocyanide gives  $Ph_3C.SCN$ .

**TRI-BROMO-DI-PHENYL-METHYL-AMINE** v. TRI-BROMO-METHYL-DI-PHENYL-AMINE

**BROMO-PHENYL-METHYL-FURFURANE** **TETRA-BROMIDE**  $C_{11}H_5Br_4O$ . [210°]. Bronzy plates. Formed by the action of bromine on

**BROMO-PHENYL-METHYL-PYRAZOLONE** v. BROMO-OXY-PHENYL-METHYL-PYRAZOL.

**$\gamma$ -BROMO- $\gamma$ -PHENYL-DI-METHYL-SUCCINIC ACID**  $Ph.CHBr.CH(CO_2H).CHMe.CO_2H$ . From the lactone of  $\gamma$ -oxy- $\gamma$ -phenyl-di-methyl-succinic acid (*q. v.*) and conc.  $HBr$  at 0° (Fittig a. Penfield, *A.* 216, 123). Small crystals (from benzene). V. sol. alcohol or ether, m. sol. benzene. Warmed with water it gives off  $CO_2$  and forms plates of an acid which appears to be  $Ph.CH:CH.CHMe.CO_2H$ .

**TETRA-BROMO-PHENYL-METHYL-THIO-PHENE**  $C_{11}H_5Br_4S$ . [187°]. Formed by bromination of phenyl-methyl-thiophene. Fine needles or plates. V. sol. benzene, ether, and petroleum-spirit, m. sol. alcohol and acetic acid (Paal a. Püschel, *B.* 20, 2559).

**BROMO-PHENYL-METHYL-URETHANE** v. Methyl ether of BROMO-PHENYL-CARBAMIC ACID.

**BROMO-PHENYL-MUSTARD OIL** v. BROMO-PHENYL-THIO-CARBIMIDE.

**DI-BROMO-PHENYL-( $\beta$ )-NAPHTHYL-AMINE**  $C_{16}H_{13}Br_2NH$ . [140°]. White needles. Prepared by bromination of phenyl-( $\beta$ )-naphthyl-amine (Streiff, *B.* 13, 1853; *A.* 209, 158).

**Tetra-bromo-phenyl-( $\beta$ )-naphthyl-amine**  $C_{16}H_9Br_4NH$ . [198°]. Sl. sol. alcohol, ether and  $C_6H_6$ , m. sol.  $CS_2$  and  $CHCl_3$ . Prepared by further bromination of the dibromo-derivative.

**Tri-bromo-phenyl-( $\alpha$ )-naphthyl-amine**  $C_{16}H_9Br_3NH$ . [137°]. Colourless prisms. Soluble in alcohol and benzene. Prepared by bromination of phenyl-( $\alpha$ )-naphthylamine (S.).

**Tetra-bromo-phenyl-( $\beta$ )-naphthyl-amine**  $C_{16}H_9Br_4NH$ . [203°]. Formed by the action of bromine upon an acetic acid solution of benzene-azo-phenyl-( $\beta$ )-naphthyl-amine, or by bromination of phenyl-( $\beta$ )-naphthyl-amine. Long white silky needles (Zincke a. Lawson, *B.* 20, 1170).

**BROMO-PHENYL-OCTANE** v. BROMO-OCTYL-BENZENE.

***p*-BROMO-PHENYL-OXAMIC ACID**  $C_6H_4Br.NH.CO.CO_2H$ . [198°]. S. 191 at 25°. From di-bromo-di-phenyl-oxamide and alcoholic KOH (Dyer a. Mixer, *Am.* 8, 355). Crystalline fibres, sol. alcohol and ether. KOHAq liberates *p*-bromo-aniline. Salts.— $KA'$ : monoclinic scales.— $CaA'_2$ — $AgA'$ — $BaA'_2$ .

*Ethyl ether*  $EtA'$ . [156°]. From phenyl-oxamic ether and Br (Klingor, *A.* 184, 263).

**DI-BROMO-DI-PHENYL-OXAMIDE**  $(C_6H_4Br.NH)_2C_2O_2$ . [above 300°]. From Br and di-phenyl-oxamide in HOAc (D. a. M.).

**DI-BROMO-DI-PHENYL OXIDE**  $(C_6H_4Br)_2O$ . [58°]. (above 360°). From Br and di-phenyl oxide in  $CS_2$ . Long plates (from alcohol) (Merz a. Weith, *B.* 14, 191).

**TRI-BROMO-TRI-PHENYL PHOSPHATE**  $(C_6H_4BrO)_3PO$ . From tri-phenyl phosphate and Br at 180°. Nacreous scales (Glutz, *A.* 143, 193).

***p*-BROMO-PHENYL-PHTHALIMIDE**  $C_6H_4 \begin{array}{c} C=O \\ \diagup \quad \diagdown \\ C=O \end{array} N.C_6H_4Cl$  [204°]. Fine flat

needles or scales. Sol.  $C_6H_6$  and acetic acid, less in ether. Prepared by heating *p*-brom-aniline with phthalic anhydride (Gabriel, *B.* 11, 2261).

**BROMO-PHENYL-PROPANE** v. BROMO-PROPYL-BENZENE.

***o*-BROMO- $\beta$ -PHENYL-PROPIONIC ACID**  $[2:1] C_6H_4Br.C_2H_4.CO_2H$ . *o*-Bromo-hydrocinnamic acid. [99°]. Sol. Scales. Formed by reduction of *o*-bromo-cinnamic acid with HI and P (Gabriel, *B.* 15, 2295).

***m*-Bromo- $\beta$ -phenyl-propionic acid**  $[3:1] C_6H_4Br.C_2H_4.CO_2H$ . *m*-Bromo-hydrocinnamic acid. [75°]. Formed by reduction of *m*-bromo-cinnamic acid with P and HI. Also by eliminating the  $NH_2$  group from (3:4:1)-bromo-amido-phenyl-propionic acid by diazotising and treatment with alcohol (Gabriel, *B.* 15, 2294).

Short thick prisms. V. sol. alcohol, ether, benzene, chloroform, and  $\text{CS}_2$ .

***p*-Bromo- $\beta$ -phenyl-propionic acid**

[4:1]  $\text{C}_6\text{H}_4\text{Br}.\text{CH}_2.\text{CH}_2.\text{CO}_2\text{H}$ . [135°]. From  $\beta$ -phenyl-propionic acid and Br in the cold (Göring, *C. C.* 1877, 793, 808; Gabriel a. Zimmermann, *B.* 13, 1683). Flat needles (from  $\text{CS}_2$ ). Oxidation gives *p*-bromo-benzoic acid.

***\beta*-Bromo- $\beta$ -phenyl-propionic acid**

$\text{C}_6\text{H}_5.\text{CHBr}.\text{CH}_2.\text{CO}_2\text{H}$ . [137°]. From cinnamic acid and HBr (Fittig a. Binder, *B.* 10, 518; *A.* 195, 132; Anschütz a. Kinnicutt, *B.* 11, 1221). Also from  $\beta$ -bromo- $\beta$ -oxy-phenyl propionic acid and HBr (Glaser, *A.* 147, 96). Lamine. Decomposed by heat into HBr and cinnamic acid. Boiling water forms  $\beta$ -oxy- $\beta$ -phenyl-propionic acid. Cold NaOH aq gives styrene and  $\text{CO}_2$ .

***\alpha*-Bromo- $\alpha$ -phenyl-propionic acid**

$\text{CH}_3.\text{CPhBr}.\text{CO}_2\text{H}$ . *Bromo-hydratropic acid*. [94°]. From atropic or atrolactic acids and cold conc. HBr aq (Fittig a. Wurster, *A.* 195, 145; Merling, *A.* 209, 13). Tables, insol. water, sol. ordinary solvents. Boiling  $\text{Na}_2\text{CO}_3$  aq produces atrolactic acid.

***\beta*-Bromo- $\alpha$ -phenyl-propionic acid**

$\text{CH}_2\text{Br}.\text{CHPh}.\text{CO}_2\text{H}$ . [94°]. Formed by heating atropic acid with conc. HBr aq at 100°. Prisms, insol. water. Boiling  $\text{Na}_2\text{CO}_3$  aq produces tropic acid, styrene, and a very little atropic acid. Ammonia forms  $\beta$ -amido- $\alpha$ -phenyl-propionic acid [169°] (M.).

***\alpha\beta*-Di-bromo- $\beta$ -phenyl-propionic acid**

$\text{C}_6\text{H}_5.\text{CHBr}.\text{CHBr}.\text{CO}_2\text{H}$ . [195°] (G.); [201°] (S.). From cinnamic acid and bromine-vapour (Schmidt, *A.* 127, 320; Fittig a. Binder, *A.* 195, 140). Also from  $\alpha$ -bromo- $\beta$ -oxy-phenyl-propionic acid and HBr (Glaser, *A.* 147, c.). Lamine (from alcohol); v. sol. ether and alcohol, v. sl. sol.  $\text{CS}_2$ .

**Reactions.**—1. Sodium amalgam forms phenyl-propionic acid.—2. Boiling water gives cinnamic acid, bromo-oxy-phenyl-propionic acid, phenyl-acetic aldehyde and  $\omega$ -bromo-styrene. 3. Alcoholic KOH gives  $\alpha$ - and  $\beta$ -bromo-cinnamic acids.

**Salts.**— $\text{NaA}'$ .— $\text{BaA}'$ .

**Methyl ether**  $\text{MeA}'$ . [117°] (Anschütz, *B.* 12, 538).

**Ethyl ether**  $\text{EtA}'$  [69°]. From cinnamic ether and bromine (Perkin, jun., *C. J.* 45, 172).

***n*-Propyl ether**  $\text{PrA}'$ . [23°].

***\alpha\beta*-Di-bromo- $\alpha$ -phenyl-propionic acid**

$\text{CH}_2\text{Br}.\text{CPhBr}.\text{CO}_2\text{H}$ . [116°]. From Br and atropic acid in  $\text{CS}_2$  (Fittig a. Wurster, *A.* 195, 145). Needles (from  $\text{CS}_2$ ). Decomposed by boiling water into  $\text{CO}_2$ , HBr, and acetophenone. Sodium-amalgam forms  $\alpha$ -phenyl-propionic acid and oxy-phenyl-propionic acid. Excess of NaOH aq gives atrogyric acid  $\text{C}_6\text{H}_5\text{O}_4$  (Fittig a. Kast, *A.* 206, 30).

**Tri-bromo-phenyl-propionic acid**

$\text{C}_6\text{H}_5.\text{CHBr}.\text{CBr}.\text{CO}_2\text{H}$ . [151°]. From bromo-cinnamic acid [120°] and Br (Glaser, *A.* 143, 335; Stockmeier, *Bn.* 2, 872; Kinnicutt, *Am.* 4, 26). Small flat monoclinic needles (from dilute alcohol). Boiling water gives  $\text{CO}_2$ , di-bromo-styrene, bromo-cinnamic acid, and di-bromo-oxy-phenyl-propionic acid.

**Tri-bromo-phenyl-propionic acid**

$\text{C}_6\text{H}_5.\text{CBr}_2.\text{CHBr}.\text{CO}_2\text{H}$ . [148°]. Formed by the combination of the bromo-cinnamic acid [159°]

with Br. Triclinic prisms. Sol. hot benzene, v. e. sol. alcohol and ether, sl. sol. cold  $\text{CS}_2$ . It decomposes at its melting-point evolving HBr. By standing for a short time with water it is converted into a neutral oil; hot water decomposes it at once (Michael a. Brown, *B.* 19, 1380).

**Tri-bromo- $\alpha$ -phenyl-propionic acid**

$\text{C}_6\text{H}_5.\text{Br}_3\text{O}$ . [150°]. From bromo-atropic acid and Br (F. a. W.). Needles (from ligetin).

***\alpha\beta*-DI-BROMO-PHENYL-PROPIONIC ALDE-**

**HYDE**  $\text{C}_6\text{H}_5.\text{CHBr}.\text{CHBr}.\text{CHO}$ . *Cinnamic aldehyde dibromide*. [c. 100°]. Small needles. Formed by the direct combination of cinnamic aldehyde and bromine. It readily splits off HBr on heating, giving bromo-cinnamic aldehyde (Zincke a. Hagen, *B.* 17, 1811).

**DI-BROMO- $\beta$ -PHENYL-PROPYL ALCOHOL**

$\text{C}_6\text{H}_5.\text{Br}_2\text{O}$ . *i.e.*  $\text{C}_6\text{H}_5.\text{CHBr}.\text{CHBr}.\text{CH}_2.\text{OH}$ . *Styrcerin dibromhydrin*. *Styrene dibromide*. [74°]. From Br and cinnamyl alcohol in  $\text{CHCl}_3$  (Grinaux, *B.* [2] 20, 120). Tables or needles (from ether). Insol. water. Boiling water converts it into  $\text{C}_6\text{H}_5.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}_2.\text{OH}$ .

**Acetyl derivative**

$\text{C}_6\text{H}_5.\text{CHBr}.\text{CHBr}.\text{CH}_2.\text{OAc}$ . [86°]; prisms.

**DI-BROMO-PHENYL-PROPYLDENE-**

**ANILINE**  $\text{C}_6\text{H}_5.\text{N}:\text{CH}.\text{CHBr}.\text{CHBr}.\text{Ph}$ . [175°]. From cinnamylene-aniline and bromine (Schiff, *A.* 239, 384). Needles (from alcohol).

**DI-BROMO-PHENYL-PYRAZOL DIHY-**

**DRIDE**  $\text{C}_6\text{H}_5.\text{Br}_2\text{N}_2$ . [93°]. *Di-bromo-phenyl-pyrazoline*. From phenyl-pyrazoline and Br in chloroform (Fischer a. Knevenagel, *A.* 239, 199). Plates (from alcohol); v. sl. sol. water. In dilute acid solution it gives a violet colour with  $\text{K}_2\text{Cr}_2\text{O}_7$ . Alcoholic KOH forms  $\text{C}_6\text{H}_5.\text{Br}(\text{OH})\text{N}_2$  [66°], which crystallises from alcohol in pale yellow prisms. Boiling HCl aq gives off  $\text{EtCl}$  and forms bromo-oxy-phenyl-pyrazol  $\text{C}_6\text{H}_5.\text{Br}(\text{OH})\text{N}_2$  [214°]; this has acid characters and forms greenish-yellow crystals (from alcohol).

**DI-BROMO-( $\alpha$ )-PHENYL-PYRIDINE DI-**

**CARBOXYLIC ACID**  $\text{C}_6\text{H}_5.\text{Br}_2\text{NO}$ . [205°]. From [2:1]  $\text{C}_6\text{H}_5(\text{CO}_2\text{H}).\text{C}_6\text{H}_5\text{N}(\text{CO}_2\text{H})$  [3:2] and bromine (Skrap a. Cohenzil, *M.* 4, 469). Granules, v. sl. sol. water, m. sol. warm alcohol.

**DI-BROMO-DI-PHENYL SULPHIDE**

$(\text{C}_6\text{H}_5.\text{Br})_2\text{S}$ . [110°]. From di-phenyl sulphide and Br, or from  $(\text{C}_6\text{H}_5.\text{NH}_2)_2\text{S}$  by diazo-reaction. Naerous lamine (Krafft, *B.* 7, 1165).

**Di-*p*-bromo-di-phenyl disulphide**  $(\text{C}_6\text{H}_5.\text{Br})_2\text{S}_2$

[94°]. From *p*-bromo-phenylmercaptan by atmospheric oxidation. Plates; not volatile with steam (Hübner a. Alsberg, *I.* 156, 322; Baumann a. Preusse, *II.* 5, 329).

**DI-*p*-BROMO-DI-PHENYL SULPHONE**

$(\text{C}_6\text{H}_5.\text{Br})_2\text{SO}_2$ . [172°]. From *p*-bromo-benzene and  $\text{ClSO}_3\text{H}$  (Armstrong, *C. J.* 24, 173) or  $\text{SO}_2$  (Nölting, *B.* 8, 594). Also from bromo-benzene, benzene sulphochloride, and  $\text{Al}_2\text{Cl}_6$  (Beckurts a. Otto, *B.* 11, 2065). Needles, sl. sol. hot alcohol.

***p*-BROMO-PHENYL-THIO-CARBAMIC**

**ETHER**  $\text{C}_6\text{H}_5.\text{BrNSO}$  *i.e.*  $\text{C}_6\text{H}_5.\text{Br.NHCS.OEt}$ . *Bromo-phenyl-thio-urethane*. [105°]. From *p*-bromo-phenyl thio-carbimide and alcohol at 120° (Dennstedt, *B.* 13, 231). Slender needles.

***p*-Bromo-phenyl-di-thio-carbamic ether**

$\text{C}_6\text{H}_5.\text{Br.NHCS.SEt}$ . *Bromo-di-thio-carbanilic ether*. [89°]. From *p*-bromo-phenyl-thio-carbimide and mercaptan at 140° (D.).

***p*-Bromo-phenyl-thio-carbimide**  
 $C_6H_4Br.NCS$ . *p*-Bromo-phenyl mustard oil. [61°]. Prepared by heating *p*-bromo-aniline with  $CS_2$  in alcoholic solution with a little aqueous KOH; the resulting thio-urea being distilled with  $P_2O_5$  or heated with conc. HCl at 160° (Dennstedt, *B.* 13, 230; Weith and Landolt, *B.* 8, 716).

**DI-*p*-BROMO-DI-PHENYL-DI-THIO-CINNAMIC ALDEHYDATE**  $C_6H_4Br.C_6H_4Br.CH(S.C_6H_4Br)_2$ . *p*-Bromo-phenyl-mercaptol of cinnamic aldehyde. [107°]. Formed by passing  $H_2$  gas into a mixture of *p*-bromo-phenyl mercaptan and cinnamic aldehyde (Baumann, *B.* 18, 885). Long colourless needles. Sl. sol. cold alcohol and ether.

**BROMO-PHENYL-THIO-GLYCOLLIC ACID**  $C_6H_4Br.SO_2$  i.e.  $C_6H_4Br.S.CH_2.CO_2H$ . [112°]. From  $C_6H_4Br.S.CH_2.CO_2H$  and Br in  $CS_2$  (Clässon, *Bk.* [2] 23, 441).

**DI-*p*-BROMO-DI-PHENYL-DI-THIO-DIMETHYL-KETATE**  $(CH_3)_2C(SC_6H_4Br)_2$ . *p*-Bromo-phenyl-mercaptol of acetone. [90°]. Long transparent prisms. V. sol. hot alcohol, ether, and benzene. Formed by passing HCl gas into a mixture of *p*-bromo-phenyl-mercaptan and acetone (Baumann, *B.* 18, 888).

***p*-BROMO-PHENYL-THIO-UREA**  
 $NH_2.CS.NH.C_6H_4Br$ . [183°]. From bromo-phenyl-thio-carbimide and alcoholic  $NH_3$  (Dennstedt, *B.* 13, 231). Needles.

***p*-Bromo-di-phenyl-thio-urea**  
 $NHPh.CS.NH.C_6H_4Br$  [158°]. From bromo-phenyl-thio-carbimide and aniline (D.).

**Di-*p*-bromo-di-phenyl-thio-urea**  
 $CS(NH.C_6H_4Br)_2$ . [178°]. From *p*-bromo-aniline,  $CS_2$ , and alcohol in presence of some KOH aq (D.; Otto, *B.* 2, 409). Prisms.

**BROMO-PHENYL-THIO-URETHANE v. BROMO-PHENYL-THIO-CARBAMIC ETHER.**

**TETRA-BROMO-PHENYL-*p*-TOLUIDINE**  
 $C_6H_2Br_4.N$ . [156°]. Formed by adding a solution of Br in glacial HOAc to an alcoholic solution of phenyl-*p*-toluidine (Bonna, *A.* 239, 58).

**Hepta-bromo-phenyl-*p*-toluidine**  $C_6H_3Br_7.N$ . [185°]. From phenyl-*p*-toluidine and Br at 280°.

**Endeca-bromo-phenyl-*p*-toluidine**  
 $C_6H_2Br_{11}.N$ . [296°]. Formed from phenyl-*p*-toluidine and Br at 310°.

**BROMO-*p*-PHENYL-TOLUENE**  $C_6H_4Br$ . [127°-131°]. From *p*-phenyl-toluene and Br.

Small tables (from alcohol) (Carnelley a. Thomson, *C. J.* 47, 589).

**DI-*p*-BROMO-DI-PHENYL-UREA**  
 $C_6H_4Br_2.N_2O$  i.e.  $CO(NH.C_6H_4Br)_2$ . *Di-bromobromanilide*. From di-phenyl-thio-urea and Br (Otto, *B.* 2, 409). Formed also by decomposition of the product from  $COCl_2$  and diazobenzene-*p*-bromanilide. Prepared by the action of carbonyl chloride on *p*-bromaniline (Saraauw, *B.* 15, 45). White glistening plates. Sublimes at 225° without melting. Sl. sol. alcohol and benzene.

**Tetra-bromo-di-phenyl-urea**  
 $CO(NH.C_6H_4Br)_2$ . Sublimes in needles (O.).

**BROMO-PHENYL-URETHANE v. BROMO-PHENYL-CARBAMIC ETHER.**

**DI-BROMO-PHENYL-VALERIC ACID**  
 $C_6H_4Br.CHBr.CHBr.CH_2.CO_2H$ . [109°]. From styryl-propionic acid and Br (Baeyer a. Jackson, *B.* 13, 122).

**BROMO-PHLOBAPHENE v. PHLOBAPHENE. BROMO-PHLORETIC ACID v. PHLORETIC ACID.**

**TRI-BROMO-PHLOROGLUCIN**  $C_6Br_3(OH)_3$ . [151°]. Formed by brominating phloroglucin (Hlasiwetz, *A.* 96, 118; Herzig, *M.* 6, 885). Long needles (containing 3aq) (from water). Reduced by tin and HCl to phloroglucin. Converted by cold  $HNO_3$  (S.G. 1.4) into tri-bromo-di-nitro-propionic acid (Benedikt, *A.* 184, 255).

*Tri-acetyl derivative*  $C_6Br_3(OAc)_3$ . [183°] (Herzig, *M.* 6, 887).

**Hexa-bromo-phloroglucin dibromides**  
 $C_6Br_3(OBr)_2$ . [118°]. The final product of the bromination of phloroglucin (Hazura a. Benedikt, *M.* 6, 702). Small golden needles (from  $CHCl_3$ ). At 190° it gives off Br (1 mol.). Aqueous  $SO_2$  reduces it to  $C_6Br_3(OH)_3$ . Tin and HCl form  $C_6H_3Cl_3(OH)_3$ .

**DI-*iso*-BROMO-*v*-PHOSPHO-AMIDO-BENZENE SULPHONIC ACID**

$(HO)_2PO.NH.C_6H_4Br.SO_3H$ . The *chloride*  $Cl_2P.O.NH.C_6H_4Br.SO_3Cl$  is formed by treating di-bromo-amido-benzene sulphonic acid with  $PCl_5$ . It is converted by alcohol into the *ether-chloride*  $(EtO)_2P.O.NH.C_6H_4Br.SO_3Cl$  [c. 170°] (Laar, *J. pr.* [2] 20, 257).

**BROMO-PHTHALACENE v. PHTHALACENE.**

***i*-BROMO-PHTHALIC ACID**  $C_6H_4Br(CO_2H)_2$ . [134°]. [140°]. Formed, together with its isomeride, by brominating phthalic acid (Faust, *A.* 160, 62; Pechnmann, *B.* 12, 2124; cf. Guareschi, *A.* 222, 295, Stallard, *C. J.* 49, 187). Powder, v. sol. water, alcohol, and ether.

**Salts.**— $K_2A''$  2aq: long needles (from alcohol).— $BaA''$  2aq: crystalline powder; sl. sol. water.— $CuA''$ — $Ag_2A''$ : cheesy pp., sl. sol. water. *Anhydride*  $C_6H_3Br(CO)_2O$ . [65°]. (300°-340°).

*Ethyl ether*  $Et_2A''$ : (295°); liquid.

*c*-Bromo-phthalic acid  $C_6H_3Br(CO_2H)_2$  [1:2:3]. [176°] (G.); [174°] (M.); [197°] (C. a. T.).

**Formation.**—1. Together with the preceding, by brominating phthalic acid (Pechmann).—2. By the oxidation of bromo-nitro-naphthalene [122-5°] with  $KMnO_4$  (Guareschi, *A.* 222, 292), of bromo-(*β*)-naphthol with  $KMnO_4$  (Meldola, *C. J.* 47, 512), of liquid bromo-ditolyl (Carnelley a. Thomson, *C. J.* 47, 591), of di-bromo-naphthalene [130°] with  $CrO_3$  in  $HOAc$  (Guareschi, *B.* 19, 134), of  $C_6H_4Br(OH)$  [1:3:4:2] with  $KMnO_4$  (Smith, *C. N.* 40, 87), and of (*α*)-bromo-naphthalene, and bromo-*o*-toluic acid [167°] with dilute  $HNO_3$  (Racine, *A.* 239, 76). The bromo-*o*-toluic acid may be prepared from bromo-*o*-toluidine  $C_6H_4McBr(NH_2)$  [1:5:2] by Sandmeyer's method; 70 g. of bromo-toluidine gave 53 g. of bromo-phthalic acid.

**Properties.**—White prisms (from water); v. sl. sol. chloroform, m. sol. water, alcohol, and ether. With resorcin it gives a fluorescein (Nourisson, *B.* 20, 1010). The salt  $BaA''$  forms pearly plates, sl. sol. water.

*Anhydride*  $C_6H_3Br(CO)_2O$ . [135°] (Meldola); [132°] (G.); [125°] (Smith); [108°] (Nourisson); [95°] (Racine). Needles. Heated with phenol and  $H_2SO_4$  it forms a body (? bromo-phthalide) that dissolves in alkalis forming a purple solution.

**Di-bromo-phthalic acid**  $C_6H_2Br_2(CO_2H)_2$  [1:4:2:3]. [135°]. From di-bromo-naphthalene

[82°] and  $\text{HNO}_3$ . White crystalline powder, sol. boiling water and alcohol (Guareschi, A. 222, 274). On melting it changes to its anhydride.

Salt.— $\text{Na}^+\text{A}^-$ .

**Anhydride**  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO})_2\text{O}$  [208°]. Pearly needles (by sublimation). Heated with phenol and  $\text{H}_2\text{SO}_4$  it forms a product (dibromophthalin) that dissolves in potash forming a purple solution.

**Di-bromo-phthalic acid**  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$  [206°]. Formed by oxidation of penta-bromo-(a)-naphthol or of tetra-bromo-(a)-naphthoquinone by means of dilute  $\text{HNO}_3$  at 150° (Blümlein, B. 17, 2490). Colourless needles. V. e. sol. alcohol, ether, and hot water.

Salts.— $\text{A}^+\text{Ag}^-$ : small colourless plates, sparingly soluble.  $\text{A}^+\text{Ca}^-$ : pp.  $\text{A}^+\text{Ba}^-$ : pp.

**Anhydride**  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO})_2\text{O}$  [208°]. Sublimes in long colourless needles. Easily soluble in alcohol, sparingly in water and ether. Formed by heating the acid. Heated with resorcin it yields a di-bromo-fluorescein.

**Di-bromo-tetra-hydro-phthalic acid**  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$ . **Di-bromo-tetra-hydro-benzene-di-o-carboxylic acid**. \*Formed by the direct combination of dry di-hydro-phthalic acid with bromine vapour. Rhombohedra (Bayer, B. 19, 1810).

**Tri-bromo-phthalic acid**  $\text{C}_6\text{HBr}_3(\text{CO}_2\text{H})_2$  [191°]. Formed by oxidation of penta-bromo-(β)-naphthol or of tetra-bromo-(β)-naphthoquinone with  $\text{HNO}_3$  (Flossa, B. 17, 1482). Small silvery plates or needles. Nearly insoluble in petroleum ether and in cold water.

Salts.— $\text{Ag}^+\text{A}^-$ .— $\text{Ca}^+\text{A}^-$  2aq.— $\text{Ba}^+\text{A}^-$  2aq.

**Anhydride**  $\text{C}_6\text{HBr}_3(\text{CO})_2\text{O}$  [157°]; sublimes in white plates; easily soluble in alcohol and ether, nearly insoluble in cold water.

**Tetra-bromo-phthalic acid**  $\text{C}_6\text{Br}_4(\text{CO}_2\text{H})_2$  [266°]. Formed by oxidation of tetra-bromo-o-xylene by heating with dilute  $\text{HNO}_3$  and bromine at 170° (Blümlein, B. 17, 2493). Small needles or colourless prisms. V. sl. sol. water. With resorcin it yields a tetra-bromo-fluorescein.

Salts.— $\text{A}^+\text{Ca}^-$ .— $\text{A}^+\text{Ba}^-$ .

**Anhydride**  $\text{C}_6\text{Br}_4(\text{CO})_2\text{O}$  [259°]. Formed by heating the acid. Sublimes in colourless glistening needles. Sl. sol. almost all solvents. V. also BROMO-TEREPHTHALIC ACIDS.

**BROMO-PHTHALIDE**  $\text{C}_6\text{H}_3\text{Br}(\text{CH}_2\text{CO})_2\text{O}$ .

[806°]. [100°]. Formed in small quantity, together with bromo-o-toluic acid, by the action of bromine-water on o-toluic acid (Racine, A. 239, 76). Needles (from dilute alcohol); sublimes readily. Insol. cold water or  $\text{Na}_2\text{CO}_3$  aq. Gives bromo-o-toluic acid [167°] on oxidation.

(a)-Bromo-phthalide  $\text{C}_6\text{H}_4(\text{CHBrCO})_2\text{O}$  [86°]. From phthalide and bromine at 140° (Racine, A. 239, 79; B. 19, 778). Small cubes or tables (from ether). May be distilled. Hygroscopic. Slowly decomposed by cold, quickly by hot water, forming phthalic aldehyde-acid  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})(\text{CHO})$ . Alcohol converts it into  $\text{C}_6\text{H}_4(\text{CO}_2\text{Et})(\text{CHO})$ .  $\text{KMnO}_4$  oxidises it to phthalic acid. Ammonia forms amido-phthalide,  $\text{C}_6\text{H}_4(\text{CH}(\text{NH}_2)\text{CO})_2\text{O}$  [167°].

**Di-bromo-phthalide**  $\text{C}_6\text{H}_2\text{Br}_2\text{O}$ , i.e.

$\text{C}_6\text{H}_2\text{Br}_2(\text{CH}_2\text{CO})_2\text{O}$  [188°]. S. (94 p.p. alcohol) 37 at 15°. From di-bromo-naphthalene,  $\text{CrO}_3$  and glacial acetic acid (Guareschi, A. 222, 282). Prisms or needles (from alcohol). Neutral reaction. Does not reduce ammoniacal  $\text{AgNO}_3$ . With phenol and  $\text{H}_2\text{SO}_4$  gives no dye on heating.

**DI-BROMO-PICENE** v. PICENE.

**BROMO-PICEN** v. TRI-BROMO-NITRO-METHANE.

**BROMO-PIPERIDIN-3-HYDROXYLIC ACID** v. BROMO-DI-OXY-PHENYL-VALERIC ACID.

**BROMO-PIPERIC ACID** *Dihydride*.

$\text{C}_{12}\text{H}_{11}\text{BrO}_2$  or

$\text{CH}_2(\text{O})\text{C}_6\text{H}_4\text{Br}.\text{CH}_2.\text{CH}_2.\text{CH}(\text{O})\text{C}_6\text{H}_4\text{H}$ .

**Bromo-(β)-hydro-piperic acid**. [171°]. From bromine and (β)-di-hydro-piperic acid (Fittig a. Buri, A. 216, 177; Weinstein, A. 227, 42). Streaky white plates (from benzene).—Salt.— $\text{CaA}'$ .

**Reactions**.—1. Not affected by boiling aqueous  $\text{KOH}$ .—2.  $\text{KMnO}_4$  oxidises it, in neutral solution, to bromo-piperonylic acid [204°], bromo-piperopropionic acid (q. v.) and bromo-piperonal; hence it is in the benzene nucleus.—3. **Sodium-amalgam** forms piperhydronic or methylene-di-oxy-phenyl-valeric acid  $\text{C}_{12}\text{H}_{11}\text{O}_4$ .

**DI-BROMO-PIPERINIDE** v. BROMO-TRI-OXY-PHENYL-VALERIC ACID.

**BROMO-PIPERONYLIC ACID** v. BROMO-DI-OXY-BENZOIC ACID.

**BROMO-PIPERO-PROPIONIC ACID** v. *Methylene derivative of* BROMO-DI-OXY-PHENYL-PROPIONIC ACID.

**DI-BROMO-PREHNITOSE** v. DI-BROMO-DURENE.

**BROMO-PROPANE** v. PROPYL BROMIDE.

**Di-bromo-propane**  $\text{C}_3\text{H}_4\text{Br}_2$ , i.e.

$\text{CH}_2.\text{CHBr}.\text{CH}_2$  tr. (141.5°). *Propylene bromide*. S.G. 1.9617 (Zander, A. 214, 175). S.V. 118.9 (Z.); 118.4 (Schiff).

**Formation**.—1. From propylene and Br (Reynolds, A. 77, 120; Cahours, C. R. 31, 291; Wurtz, A. 104, 244).—2. From bromo-propylene and HBr.—3. Together with trimethylene bromide by the union of HBr with allyl bromide (Geromont, Bl. [2] 16, 113, Roboul, Bl. [2] 17, 350).—4. From propyl bromide and Br (Linnemann, A. 161, 41).

**Properties**.—Liquid with sweet smell.

**Reactions**.—1. Alcoholic  $\text{KOH}$  forms two bromo-propylenes and, finally, allylene (Sawitsch, C. R. 52, 399).—2.  $\text{AgOAc}$  gives the diacetyl derivative of propylene-glycol (Wurtz, A. Ch. [3] 4, 438).  $\text{AgOBz}$  gives the corresponding benzoyl derivative (Friedel a. Silva, C. R. 73, 1379).—3. Converted into propylene by Zn and HOAc or sodium-amalgam in alcohol (Linnemann, B. 10, 111).—4. Aqueous  $\text{HI}$  at 150° gives isopropyl bromide.—5. Heated to 100° with  $\text{Ag}_2\text{O}$  and water it gives propionic aldehyde but no propylene-glycol (Beilstein a. Wiegand, B. 15, 1496).—6. **Water** (20 vols.) and  $\text{PbO}$  at 150° gives acetone, propionic aldehyde and propylene-glycol (Eltekoff, J. R. 10, 212).—7. Protracted boiling with water gives propylene-glycol (Niederist, A. 190, 349).

**aa-Di-bromo-propane**  $\text{CH}_3.\text{CBr}_2.\text{CH}_3$ . *Methyl bromacetol. Bromacetol. Acetone bromide*. (115°).

S.G. 1.8476;  $d_4^{20}$  1.8314. M. M. 10-137 at 20-7° (Perkin). Formed in small quantity from acetone and PBr<sub>3</sub> or PCl<sub>3</sub>Br<sub>2</sub> (Linnemann, A. 188, 125; Friedel a. Ladenburg, Z. 1868, 48). Also from allylene and conc. HBr (Reboul, C. R. 74, 669); and from  $\alpha$ -bromo-propylene and HBr.

**Reactions.**—1. Water at 160° gives acetone.—2. Zn and HCl give propane (Linnemann, A. 161, 67).—3. Alcoholic KOH gives  $\alpha$ -bromo-propylene CH<sub>3</sub>CHBr.CH<sub>2</sub>.

#### $\omega\omega$ -Di-bromo-propane

CH<sub>3</sub>CH<sub>2</sub>CHBr<sub>2</sub> (c. 130°). From  $\omega$ -bromo-propylene CH<sub>3</sub>CHBr.CH<sub>2</sub> and conc. HBr (Reboul, A. Ch. [5] 14, 467).

#### $\omega\omega$ -Di-bromo-propane CH<sub>3</sub>CHBr.CH<sub>2</sub>Br

*Trimethylene bromide*. (65°). S.G. 2.006 (Z.);  $d_4^{20}$  2.018 (G.);  $d_4^{17.6}$  1.9228 (F.). S.V. 117.8 (Z.). Formed from  $\omega\omega$ -di-oxy-propane and HBr (Freund, M. 2, 639).

**Preparation.**—Allyl bromide is saturated with very nearly dry HBr at -16°, sealed up and left at 30° for 24 hours. The tube is opened and the operation repeated as long as any gas is absorbed (Geromont, A. 158, 370; Reboul, A. Ch. [5] 14, 472; Erlenmeyer, B. 12, 1354; A. 197, 184; Roth, B. 14, 1351; Bogomolitz, Bl. [2] 30, 23).

**Reactions.**—1. Alcoholic KOH forms allyl bromide or allyl ethyl oxide.—2. Alcoholic NH<sub>3</sub> forms some amorphous bases (Niederist, M. 3, 840).—3. Heated to 100° with Ag<sub>2</sub>O and water it gives tri-methylene-glycol thus differing from the isomeric propylene bromide which gives propionic aldehyde (Beilstein a. Wiegand, B. 15, 1496).—4. Al<sub>2</sub>Br<sub>6</sub> converts it into propylene bromide (Gustavson, J. pr. [2] 36, 303).

$\omega$ -Tri-bromo-propane CH<sub>3</sub>CHBr.CHBr<sub>2</sub> (201°). From  $\omega$ -bromo-propylene and Br (Reboul, A. Ch. [5] 14, 481).

$\omega\alpha$ -Tri-bromo-propane CH<sub>3</sub>CHBr.CH<sub>2</sub>Br (191°). S.G. 2.35. Formed by the union of bromo-propylene with Br (Reboul, A. Ch. [5] 14, 481; C. Kolbe, J. pr. 133, 393).

$\alpha$ -Tri-bromo-propane CH<sub>2</sub>Br.CHBr.CH<sub>2</sub>Br. *Tri-bromhydrin*. [17°]. S.G. 2.44.

**Formation.**—1. From di-bromhydrin or epibromhydrin and PBr<sub>3</sub> (Berthelot a. de Luca, A. 101, 76; Henry, A. 154, 369).—2. From allyl bromide and Br (Pollens, A. 156, 168).—3. By bromination of isopropyl bromide (Linnemann, A. 136, 63).—4. From allyl iodide and Br (Wurtz, A. 104, 247).

**Properties.**—Prisms or liquid.

**Reactions.**—1. Alcoholic KOH gives CH<sub>3</sub>C.CH<sub>2</sub>OEt.—2. Solid KOH gives two di-bromo-propylenes.—3. AgOAc gives triacetin C<sub>3</sub>H<sub>5</sub>(OAc)<sub>3</sub>.—4. KCy gives C<sub>3</sub>H<sub>5</sub>(C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>.—5. Alcoholic NH<sub>3</sub> forms di-bromo-di-allyl-amine and then methyl-pyridine.

**Tetra-bromo-propane** CH<sub>2</sub>Br.CBr<sub>2</sub>.CHBr<sub>2</sub>. *Allylene tetra-bromide*. (225°-230°); (110°-130°) at 10 mm. S.G. 2.94. From allylene and Br (Oppenheim, Bl. [2] 2, 6; 4, 434; A. 132, 124). Liquid, decomposed by alcoholic KOH into HBr and tri-bromo-propylene (c. 193°) (Pinner, A. 179, 59).

**Tetra-bromo-propane** CH<sub>2</sub>Br.CBr<sub>2</sub>.CH<sub>2</sub>Br. [195°]. From iso-allylene and Br (Hartenstein, J. pr. [2] 7, 817).

The following tetra-bromo-propanes have also been prepared:

(a): (251°); S.G. 2.64. From propylene bromide and Br (Reboul, A. Suppl. 1, 232).

(b): (69°); (c. 235°). By brominating isopropyl bromide (Linnemann, A. 136, 64).

(c): (226°); S.G. 2.47. From propylene bromide and Br (Cahours, A. 76, 284).

**Penta-bromo-propanes** C<sub>3</sub>H<sub>2</sub>Br<sub>5</sub>. The following have been described:

(a): (255°); S.G. 2.60. From propylene bromide and Br (Cahours, C. R. 31, 291).

(b): [173°]. From tri-bromo-propylene and Br (Pinner, A. 179, 60).

(c): CHBr<sub>2</sub>.CBr<sub>2</sub>.CHBr<sub>2</sub>. S.G. 1.3-01. From parargyl bromide and Br (Henry, B. 7, 761).

#### BROMO-PROPIOLIC ACID CBr<sub>2</sub>C.CO<sub>2</sub>H

Formed by decomposing mucobromic acid with baryta (Jackson a. Hill, B. 11, 1675; Am. 3, 121). Prisms (from ether). V. e. sol. water (crystallising therefrom with rag); may be partially sublimed at 100°. Boiling water liberates bromo-acetylene; boiling baryta forms bromo-acetylene and also malonic acid. The acid gives with di-bromo-acrylic acid a compound C<sub>4</sub>HBrO<sub>2</sub>C<sub>3</sub>H<sub>2</sub>BrO<sub>2</sub> [105°].

**Salts.**—BaAq, AgA.

**$\alpha$ -BROMO-PROPIONIC ACID** C<sub>3</sub>H<sub>5</sub>BrO<sub>2</sub> i.e. CH<sub>3</sub>CHBr.CO<sub>2</sub>H. [25°] (W.). (206° cor.). Formed by heating propionic acid (1 mol.) with Br (1 mol.) for several days at 150° (Friedel a. Machuca, C. R. 53, 408; A. 120, 286). Formed also from lactic acid and HBrAq at 100° (Kekulé, A. 130, 16).

**Reactions.**—1. Sodium-amalgam forms propionic acid.—2. Boiling water and ZnO give lactic acid. The K salt changes slowly to lactate in cold aqueous solution.—3. Alcoholic NH<sub>3</sub> forms alumine.—4. Finely divided Ag at 150° gives *s*-di-methyl-succinic acid.

**Ethyl ether** EtA. (162°); (130°) at 160 mm. S.G. 1.1-10. From the acid (Bischhoff, A. 206, 319). Also from lactic ether and PBr<sub>3</sub> (Henry, A. 156, 176). **Preparation.**—Propionic acid (300 g.) is converted into the bromide by adding amorphous phosphorus (31 g.) and slowly running in bromine (400 g.). After the evolution of HBr has ceased the mixture is brominated by heating to 40°-50° and slowly running in more bromine (640 g.). When the whole of the bromine has disappeared the bromo-propionyl bromide is converted into the ethyl ether by the addition of absolute alcohol. It is then treated with water, washed and fractionated. The yield from 300 g. of propionic acid amounts to 640 g. of boiling-point 156°-160° (Zelinsky, B. 20, 2026).

**Bromide** CH<sub>3</sub>CHBr.CO<sub>2</sub>Br. (155°). From propionyl bromide and Br; also from propionic acid, P, and Br (Weinig, A. 242, 163). ZnMe<sub>2</sub>, followed by water, gives methyl isopropyl ketone and di-methyl-isopropyl-carbinol (Kashirski, C. C. 1881, 278).

**Imide** (CH<sub>3</sub>CHBr.CO)<sub>2</sub>NH. [148°]. Formed by the action of water on the compound (C<sub>3</sub>H<sub>5</sub>NBr<sub>2</sub>) of propionitrile with Br (Engler, A. 142, 71). Needles, m. sol. hot water.

**$\beta$ -Bromo-propionic acid** CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>Br. [62°]. Small glistening plates. Formed by heating hydraerylic acid with HBr at 120° (Beckurts a. Otto, B. 18, 227).

**$\alpha\beta$ -Di-bromo-propionic acid**  
 $\text{CH}_2\text{Br}.\text{CHBr}.\text{CO}_2\text{H}$ . [64°]. (227°). S. 1945 (219-45) at 11°; S. (ether) 804 (73-04) at 10°.

**Formation.**—1. Got by oxidising di-bromo-propyl alcohol with  $\text{HNO}_3$ . The yield is bad (Münder a. Tollens, B. 5, 73; A. 167, 222).—2. Also by union of acrylic acid with Br (Caspary a. Tollens, A. 167, 256).—3. From acrolein dibromide and  $\text{HNO}_3$  (Linnemann a. Penl, B. 8, 1097).—4. By the action of  $\text{HBr}$  upon  $\alpha$ -bromo-acrylic and  $\alpha\alpha$ -di-bromo-propionic acids (Philippi a. Tollens, A. 171, 333).

**Properties.**—Monoclinic crystals (Haushofer, J. 1881, 687; Zepharovich, J. 1878, 693). It crystallises in two forms: tables [61°] and prisms [51°]; the latter slowly change into the former. The salts readily split off bromide, forming  $\beta$ -bromo-acrylic acid.

**Reactions.**—1. Converted into acrylic acid by KI and water, or by Zn and  $\text{H}_2\text{SO}_4$  (v. Zotta, A. 192, 102; C. a. I.).—2. Water at 120° gives bromo-oxy-propionic acid (Melikoff, J. R. 13, 237).

**Salts.**— $\text{AgA}'$ .— $\text{NH}_4\text{A}'$ .— $\text{KA}'$ .— $\text{CaA}'_2$ .— $2\text{aq}$ .— $\text{SrA}'_2$ .— $6\text{aq}$ .

**Methyl ether**  $\text{MeA}'$ . (205-8° cor.) (Weger, A. 221, 84).

**Ethyl ether**  $\text{EtA}'$ . (214-6° cor.).

**Allyl ether**  $\text{C}_3\text{H}_5\text{A}'$ . (215°-220°).

**Propyl ether**  $\text{PrA}'$ . (233° cor.).

**$\alpha\alpha$ -Di-bromo-propionic acid**  $\text{CH}_2\text{Br}.\text{CBr}_2.\text{CO}_2\text{H}$ . [65°] (F. a. M.); [61°] (P. a. T.). (c. 224°). From  $\alpha$ -bromo-propionic acid and Br (Friedel a. Machuca, C. R. 64, 220; Philippi a. Tollens, B. 6, 515). Trimeric tables.

**Reactions.**—1. Zn and  $\text{H}_2\text{SO}_4$  reduce it to propionic acid.—2. Alcoholic KOH gives  $\alpha$ -bromo-acrylic acid.—3.  $\text{AgO}$  forms pyruvic acid.—4. Finely divided silver in benzene gives di-methyl-maleic anhydride.—5. The salts are more stable than those of the preceding acid; but the silver salt warmed with water changes to pyruvic acid (Beckurts a. Otto, B. 18, 235).

**Salts.**— $\text{NH}_4\text{A}'$ .— $3\text{aq}$ .— $\text{NaA}'$ .— $\text{KA}'$ .— $\text{CaA}'_2$ .— $9\text{aq}$ .— $\text{SrA}'_2$ .— $6\text{aq}$ .

**Methyl ether**  $\text{MeA}'$ . (c. 177°). S.G. 2 1-901.

**Ethyl ether**  $\text{EtA}'$ . (191°). S.G. 2 1-754.

**Propyl ether**  $\text{PrA}'$ . (c. 202°). S.G. 2 1-684.  
**Isobutyl ether**  $\text{PrCH}_2\text{A}'$ . (c. 216°). S.G. 2 1-578.

**$\alpha\alpha\beta$ -Tri-bromo-propionic acid**

$\text{CH}_2\text{Br}.\text{CBr}_2.\text{CO}_2\text{H}$ . [95°].

**Formation.**—1. By oxidation of acrolein bromide (Linnemann a. Penl, B. 8, 1097).—2. From  $\alpha$ -bromo-acrylic acid and Br (Mauthner a. Suida, M. 2, 99; Michael a. Norton, Am. 2, 17).

**Properties.**—Monoclinic prisms:  $\alpha:b:c = 1.83:1:315$ ;  $\beta = 66^\circ$ ; m. sol. water, v. sol. alcohol and ether. On heating the Ba salt  $\text{CH}_2\text{Br}.\text{CBr}_2$  is formed. Alcoholic KOH gives  $\alpha\beta$ -di-bromo-acrylic acid.

**Salt.**— $\text{BaA}'_2$ .— $2\text{aq}$ : needles.

**$\alpha\beta\beta$ -Tri-bromo-propionic acid**

$\text{CHBr}_2.\text{CHBr}.\text{CO}_2\text{H}$ . [118°]. Prepared by heating  $\alpha\beta$ -di-bromo-acrylic acid for eight hours with conc.  $\text{HBrAq}$  (Hill a. Andrews, Am. 4, 180; P. Am. A. 17, 133). Rectangular plates, v. sol. hot water, ether, and alcohol.— $\text{AgA}'$ : small rhombic plates.— $\text{CaA}'_2$ .— $2\text{aq}$ .

**Tetra-bromo-propionic acid**  $\text{C}_2\text{HBr}_4.\text{CO}_2\text{H}$  i.e.  $\text{CHBr}_2.\text{CBr}_2.\text{CO}_2\text{H}$ . [120°]. Prepared by the combination of  $\alpha\beta$ -di-bromo-acrylic acid with Br.

Triclinic prisms: v. e. sol. alcohol and ether. The Ba salt is decomposed by boiling water with formation of tri-bromo-ethylene. Alcoholic KOH gives tri-bromo-acrylic acid.

**Salts.**— $\text{AgA}'$ .— $\text{KA}'$ .— $2\text{aq}$ .— $\text{BaA}'_2$ .— $4\text{aq}$ .— $\text{CaA}'_2$ .— $\text{aq}$  (Mauthner a. Suida, M. 2, 107; Hill a. Mabery, P. Am. A. 17, 140; Am. 4, 266; 5, 251).

**$\alpha\beta$ -DI-BROMO-PROPIONIC ALDEHYDE**  
 $\text{CH}_2\text{Br}.\text{CHBr}.\text{CHO}$ . *Acrolein dibromide*. (c. 82°) at 5 mm. (Grimaux a. Adam, Bl. [2] 36, 136). From acrolein and Br (Aronstein, A. Suppl. 3, 185; Henry, J. 7, 1112; Linnemann a. Penl, B. 8, 1097). Pungent oil. Reduces Fehling's solution. Readily polymerises, becoming crystalline [84°] in presence of  $\text{HCl}$ .  $\text{HNO}_3$  oxidises it to di- and tri-bromo-propionic acids.

**Tri-bromo-propionic aldehyde.** A liquid combination of this body with propyl alcohol  $\text{CBr}_2\text{CH}(\text{OH})(\text{OPr})$  appears to be formed on treating propyl alcohol with Br (Hardy, C. R. 79, 806).

**$\gamma$ -BROMO-n-PROPYL-ACETO-ACETIC ETHER**  $\text{CH}_2\text{Br}.\text{CH}_2.\text{CH}_2.\text{CH}(\text{CO}.\text{CH}_3).\text{CO}.\text{Et}$ . Liquid. Insol. water, sol. alcohol and ether. Heavier than water.

**Preparation.**—6 grms. of sodium are dissolved in 60 grms. of absolute alcohol and added to 32 grms. of aceto-acetic ether. The sodium-aceto-acetic ether is then added to 80 grms. of tri-methylene bromide and heated on the water-bath for half an hour; the yield is 75 p.c. of the theoretical.

**Reactions.**—By boiling with dilute acids it yields acetyl-butyl bromide and finally acetyl-butyl alcohol  $\text{C}_4\text{H}_9.\text{CO}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{OH}$ . Alcoholic  $\text{NH}_3$  eliminates  $\text{HBr}$  forming so-called 'tri-methylene-aceto-acetic ether' (Lipp, B. 18, 3277. V. also pp. 24 and 40 *supra*).

**$\beta$ -BROMO-PROPYL ALCOHOL**  $\text{C}_3\text{H}_7\text{Br}$  i.e.  $\text{CH}_2\text{Br}.\text{CH}_2.\text{CH}_2.\text{OH}$ . *Bromhydrin of tri-methylene glycol*. (98°-112°, at 185 mm. S.G. 2 1-537. S. 17 at 15°. From tri-methylene glycol (s-dioxy-propane) and  $\text{HBr}$  (Fritthling, M. 3, 697).

**$\alpha$ -Bromo-isopropyl alcohol**

$\text{CH}_3.\text{CH}(\text{OH}).\text{CH}_2\text{Br}$  (?). *Bromhydrin of Propylene glycol*. (145°-148°). From propylene oxide and  $\text{HBr}$  (Markownikoff, Z. 1870, 423).

**$\alpha\beta$ -Di-bromo-propyl-alcohol**

$\text{CH}_2\text{Br}.\text{CHBr}.\text{CH}_2\text{OH}$ . *Dibromide of allyl alcohol*. (219°) (Weger, A. 221, 83). V. p. 134.

**Methyl derivative**  $\text{CH}_2\text{Br}.\text{CHBr}.\text{CH}_2\text{OMe}$  (185°) (Henry, B. 5, 455).

**Ethyl derivative**  $\text{CH}_2\text{Br}.\text{CHBr}.\text{CH}_2\text{OEt}$  (194°).

**$\delta$ -Di-bromo-isopropyl alcohol**

$\text{CH}_2\text{Br}.\text{CH}(\text{OH}).\text{CH}_2\text{Br}$ . *Di-bromhydrin of Glycerin*. (219°). S.G. 2 2-1. From glycerin and  $\text{PBr}_3$  (Berthelot a. de Lury, A. Ch. [3] 48, 313; Reboul, A. Ch. [3] 60, 32). Also from glycerin and Br (Barth, A. 121, 349). V. also GLYCERIN.

**DI-BROMO-PROPYL-AMINE**  $\text{C}_3\text{H}_7\text{Br}_2$  i.e.  $\text{CH}_2\text{Br}.\text{CHBr}.\text{CH}_2.\text{NH}_2$ . From allylamine hydrochloride and Br. Oil. Salts.— $\text{B}'\text{HCl}$ : needles.— $\text{B}'_2\text{H}_2\text{P}(\text{Cl})_2$  (Henry, B. 8, 399).

**BROMO-PROPYL-BENZENE** v. Bromocumene.

**Di-bromo-p-di-propyl-benzene**  $\text{C}_6\text{H}_4\text{Br}_2\text{Pr}_2$ . [48°]. From di-propyl-benzene and Br (H. Körner, A. 216, 227). Needles or rectangular tables (from alcohol).

**BROMO-PROPYL-BENZOIC ACID** v. **BROMO-CUMINIC ACID**.

**DI-BROMO-PROPYL BORATE**  
 $B(O.C_2H_4.CHBr.CH_2Br)_3$ . Hexabromide of ALLYL BORATE (q. v.). Oil.

**BROMO-PROPYL BROMIDE** v. **DI-BROMO-PROPANE**.

**TETRA-BROMO-DI-PROPYL-CARBINOL** v. *Tetra-bromo-heptyl-alcohol*.

**BROMO-PROPYLENE**  $C_3H_4Br$  i.e.  $CH_2.CH:CHBr$ . (60°). S.G. 29 1.43. Formed, together with  $CH_3.CBr.CH_3$ , by heating propylene bromide with alcoholic KOH (Reboul, *A. Ch.* [5] 14, 479). \*One of the products obtained by boiling  $\alpha$ -di-bromo-butyric acid with aqueous  $Na_2CO_3$ . HBr reunites with it forming chiefly propylene bromide, but the combination is very much slower than with its isomeride (48°). Alcoholic KOH gives allylene. Br forms  $CH_3.CBr.CH_2Br$  (201°).

$\alpha$ -Bromo-propylene  $CH_3.CBr.CH_2$ . (18°). S.G. 2 1.39. Formed as above (Reynolds, *A.* 77, 122). Also by the action of alcoholic KOH on  $CH_3.CBr.CH_3$  (Reboul); and by union of HBr with allylene (Reboul, *C.* 74, 669). Oil. Readily combines with HBr forming  $CH_3.CBr_2.CH_3$ . Br forms  $CH_3.CBr_2.CH_2Br$  (191°). Mercuric acetate in HOAc at 100° forms acetone. Bromo-propylene  $CH_2Br.CH:CH_2$  v. **ALLYL BROMIDE** p. 135.

Di-bromo-propylene  $C_3H_2Br_2$  i.e.  $CH_2.CBr.CH_2Br$ . (140°-143°). (*a*)-*Epi-dibromohydrin*. From  $CH_2Br.CHBr.CH_2Br$  and solid KOH (Henry, *A.* 154, 371; *B.* 14, 401) or sodium in ether (Tollens, *A.* 156, 188). Converted by water at 130° into bromo-allyl alcohol.

Di-bromo-propylene  $CHBr.CH:CHBr$ . (152°). S.G. 11 2.06. Formed, together with the preceding and propargyl bromide, from *s*-tri-bromo-propane and KOH (Reboul, *A. Suppl.* 1, 230; Henry, *B.* 5, 186, 452). Alcoholic  $AgNO_3$  forms  $CHBr.CH:CH_2NO_3$ ;  $AgOAc$  and potassium sulphocyanide also form *B*-bromo-allyl salts.

Di-bromo-propylene  $CH_2.CBr.CHBr$ . *Allylene di-bromide*. (132°). S.G. 2 2.05. From allylene and Br (Oppenheim, *Bl.* [2] 2, 6; 4, 431; *A.* 132, 126). Also from  $CH_3.CHBr.CH_2Br$  and  $AgOAc$  at 120° (Linnemann, *A.* 136, 56).

Tri-bromo-propylene  $CH_3.CBr_2.CBr_2$  (?). (184°) (O.); (c. 193°) (P.). From allylene tetrabromide and alcoholic KOAc (O.) or aqueous NaOH (Pinner, *A.* 179, 59).

Tri-bromo-propylene  $CH_2Br.CBr_2.CHBr$ . S.G. 19 2.53. *Propargyl tribromide*. From propargyl bromide and Br. Non-volatile oil (Henry, *B.* 7, 761).

Penta-bromo-propylene  $C_3HBr_5$ . From allyl bromide, Br, and I at 210°. Non-volatile oil (Merz a. Weith, *B.* 11, 2243).

**BROMO-PROPYLENE-GLYCOL** v. **GLYCERIN**.

**BROMO-PROPYLENE-UREA**  $C_3H_4Br.N$  i.e.  $CO < \begin{smallmatrix} NH \\ NH \end{smallmatrix} > C_3H_4Br$  (?). [120°]. Formed by warming an aqueous solution of di-bromo-propylene (Andreasch, *M.* 6, 40). Silky needles; sl. sol. cold water. —  $BHCl$ : [143°]. —  $BHBr$ : [158°]. —  $B'H_2PtCl_6$ .

**DI-BROMO-PROPYL-MALONIC ACID**  
 $C_6H_4Br_2O_4$  i.e.  $(CO_2H).CH_2.CHBr.CH_2Br$ . [121°]. From allyl-malonic acid and Br in  $CS_2$  (Hjelt, *A.* 216, 58; *B.* 15, 624). Needles in stars

(from ether). V. s. sol. ether, m. sol. water. Boiled with baryta, it forms di-oxy-propyl-malonate of barium (q. v.).

**BROMO-PROPYL-PHENOL** v. **BROMO-CUMENOL**.

**BROMO-PROPYL-THIOPHENE**

$C_5SH_4(C_2H_4)Br$ . (189°). Colourless oil. Formed by bromination of *n*-propyl-thiophene (Ruffi, *B.* 20, 1741).

Di-bromo-propyl-thiophene  $C_5SH_2(C_2H_4)Br_2$ . (248°). Oil. Formed by bromination of propyl-thiophene with 2 mols. of bromine. By further bromination it is converted into tetra-bromo-thiophene (Ruffi, *B.* 20, 1741).

**DI-BROMO-PROPYL-UREA**  $C_3H_4Br_2.N_2O$  i.e.  $NH_2.CO.NH.CH_2.CBr.CH_2Br$ . [109°]. From allyl-urea and Br (Andreasch, *M.* 5, 38). Needles or leaflets, sl. sol. cold water. Decomposed by heating with water into the isomeric hydrobromide of bromo-propylene-urea (q. v.).

**BROMO-PYRIDINE**  $C_5NH_4Br$  [3]. (174° i.v.). S.G. 2 1.645.

*Formation*. — 1. By brominating pyridine (Hofmann, *B.* 12, 990). — 2. By the action of bromoform upon an alcoholic solution of pyrrol and NaOEt or upon potassium pyrrol in ether (Ciamicean a. Silber, *B.* 18, 721; Ciamicean a. Dennstedt, *G.* 12, 211; *B.* 15, 1173; Danesi, *G.* 12, 150).

*Properties*. — Alkaline liquid, sl. sol. water. Reduced to pyridine by zinc and HCl.

*Salts*. —  $B'H_2PtCl_6$ , 2aq: yellow monoclinic crystals,  $a:b:c = 1.207:1.1188$ .  $\beta = 107^\circ 7'$ . —  $B'HCl$ .

Di-bromo-pyridine  $C_5NH_2Br_2$  [2.6]. [111°]. (222°).

*Formation*. — 1. From pyridine and Br (Hofmann, *B.* 12, 988). — 2. Together with pyridine and mono-bromo-pyridine by the action of bromine on acetyl-piperidine (Hofmann, *B.* 16, 587; cf. Schotten, *B.* 15, 421). — 3. From tropidine hydrobromide and bromine at 170° (Ladenburg, *A.* 217, 148), di-bromo-methyl-pyridine being first formed, and ethylene bromide being the other product. — 4. Formed by heating the tri-carboxylic acid [206°].

*Properties*. — Long flat pearly needles, insol. cold water, sl. sol. cold alcohol. Very weak base (difference from bromo-pyridine).

*Salt*. —  $B'H_2ClPtCl_6$ : golden yellow needles (Pfeiffer, *B.* 20, 1349).

*Methylochloride*  $C_5NH_4Br.MeCl$ . Formed by heating di-bromo-apophyllin (q. v.) with HCl (Anderson, *A.* 94, 358; Hofmann, *B.* 14, 1498; v. Gerichten, *A.* 210, 99). Moist  $Ag_2O$  liberates an alkaline hydroxide. —  $B'MePtCl_6$ .

Di-bromo-pyridine  $C_5NH_2Br_2$ . [165°]. Formed by adding bromine to a boiling aqueous solution of pyridine-sulphonic acid. Long white needles. Begins to sublime at about 80°. Sol. water, alcohol, ether and benzene. —  $B'H_2ClPtCl_6$ , 2aq: large orange needles, sl. sol. water (Fischer a. Reimerschmid, *B.* 16, 1184; cf. Königs, *B.* 17, 589).

**DI-BROMO-PYRIDINE-BETAÏNE**

$C_5NH_2Br_2 < \begin{smallmatrix} CH_2 \\ O \end{smallmatrix} > CO$ . *Anhydride of di-bromo-oxy-pyridyl-acetic acid*. Formed by heating di-bromo-pyridine with chloro-acetic acid. —  $BHCl$ : colourless needles. —  $B'H_2ClPtCl_6$ : large soluble brown prisms (Gerichten, *B.* 15, 1258).

**BROMO-PYRIDINE DI-CARBOXYLIC ACID**  
**v. BROMO-APOPHYLLIC ACID.**

**Bromo-pyridine-di-carboxylic acid**  $C_5H_3Br(COOH)_2$ . [165°]. Formed, together with oxaly-anthranilic acid, by oxidation of (Py)-bromo-quinoline with  $KMnO_4$ . Crystals. V. sol. water, alcohol, ether, &c. It evolves  $CO_2$  at its melting-point, yielding bromo-pyridine-mono-carboxylic acid (bromo-nicotinic acid) [183°] (Claus a. Collischonn, B. 19, 2767).

**Di-bromo-pyridine-tri-carboxylic acid**  $C_5NBr_2(COOH)_3$ , [2:6:1:3:5]. [206°] anhydrous. Obtained by oxidation of di-bromo-s-tri-methyl-pyridine [81°] with  $KMnO_4$ . Flat plates (containing 4aq). V. sol. hot water, sl. sol. alcohol, nearly insol. ether.  $FeSO_4$  gives a red colouration. Heated to 165° it gives a sublimate of di-bromo-pyridine [111°].

**Salts.**— $AgA''$  aq.: crystalline powder.— $KHA''$  aq.: glistening colourless needles, sol. hot water.— $Cu_2A''$  aq.: microcrystalline blue powder (Pfeiffer, B. 20, 1347).

**$\alpha$ -BROMO- $\alpha$ -PYRIDYL- (Py. 2)-PROPIONIC ACID**  $C_5H_4BrNO_2$  i.e.  $C_5H_4N.CBr.Me.CO_2H$ . From the corresponding oxy-acid and  $PBr_3$  in  $CS_2$ .

**Salt.**— $(C_5H_4BrNO_2)HAuBr_4$  (Hardy a. Calmels, B. [2] 48, 232).

**DI-BROMO-PYROCATECHIN**  $C_8H_4Br_2(OH)_2$ .

**Di-methyl-ether**  $C_8H_4Br_2(OMe)_2$ . [93°]. Prepared by bromination of the di-methyl-ether of pyrocatechin (Tiemann a. Koppe, B. 14, 2018). Formed also by the action of Br on veratric acid. Colourless prisms. Sol. alcohol, ether and benzene.

**Tri-bromo-pyrocatechin**  $C_8H_3Br_3(OH)_2$ .

**Mono-methyl-ether**  $C_8H_3Br_3(OMe)(OH)$ . **Tri-bromo-guaiacol** [102°]. White felted needles. Formed by bromination of guaiacol (Tiemann a. Koppe, B. 14, 2017).

**Tetra-bromo-pyrocatechin**  $C_8H_2Br_4(OH)_2$  [1:2:3:4:5:6]. [193°]. Formed by bromination of pyrocatechin in chloroform solution. Colourless prisms (from acetic acid) or long fine needles (from alcohol). On oxidation it yields tetra-bromo-o-quinone  $C_8Br_4O_2$ . Bromine-water at 80° forms  $C_8H_2Br_4O$  [139°] (Zinke, B. 20, 1777; cf. Stenhouse, C. J. 27, 586; 28, 6; Hlasiwetz, A. 142, 251).

**TETRA-BROMO-PYROCROLL**  $C_{10}H_2Br_4O_2N_2$ . Formed by heating pyrocoll with bromine at 100°. Small yellow needles. Insol. alcohol, ether, chloroform and toluene, almost insol. acetic acid. By boiling with KOH it yields di-bromo-pyrrol-carboxylic acid (Ciamician a. Silber, B. 16, 2388).

**TRI-BROMO-PYROGALLOL**  $C_6H_3Br_3O_3$  i.e.  $C_6Br_3(OH)_3$ . **Tri-bromo-pyrogallol acid**. From tannin, glacial acetic acid and bromine at 100° (Stenhouse, C. J. 27, 586; 28, 7; Webster, C. J. 46, 207). From pyrogallol and Br (Hlasiwetz, A. 142, 250). Flat needles, sol. hot water. Bromine-water converts it into 'xanthogallol'  $C_6H_2Br_3O_3$  [122°] whence alkalis form  $C_6H_2Br_3O_3$  [130°] (S.).

**$\beta$ -BROMO-PYROMUCIC ACID**  $C_8H_5BrO_4$ . **Bromo-furfurane carboxylic acid** [129°]. S. 1:26 at 20°. From either di-bromo-pyromucic acid [168°], or [192°] by reduction with zinc dust and ammonia (Hill a. Sanger, A. 232, 58). On adding HCl the acid separates in matted

needles. Silky needles (from water, separating at first as an oil). Sol. chloroform and benzene, sl. sol. light petroleum or  $CS_2$ . Dry Br forms di-bromo-pyromucic acid [168°]. Dilute  $H_2SO_4$  gives bromo-fumaric acid [177°].

**Salts.**— $BaA'$  aq. S. 2:13 at 20°.— $CaA'$  3aq. S. 1:77 at 20°.— $AgA'$ .— $NaA'$ .— $KA'$ .

**Ethyl ether**  $EtA'$  [29°] (235° i.v.).

**Amide.**— $C_8H_4BrO_2NH_2$  [156°]. Silky needles (from water).

**( $\delta$ )-Bromo-pyromucic acid**  $C_8H_5BrO_4$ . [184°]. S. 22 at 16°.

**Formation.**—1. By the action of alcoholic KOH on the dibromide of pyromucic acid (Schiff a. Tassinari, B. 11, 842; G. 8, 297). An isomeride [155°] said to be formed at the same time has not been observed by others. The dibromide of pyromucic ether when saponified also produces di-bromo-pyromucic acid (Canzoneri a. Oliveri, G. 14, 172).—2. From pyromucic acid (20 g.) and Br (36 g.) at 100°, the yield being 50 p.c. of the theoretical (Hill a. Sanger, A. 232, 46; B. 16, 1130).

**Properties.**—Pearly leaflets (from water); sl. sol. cold water, cold benzene, and  $CHCl_3$ ; m. sol. alcohol and ether. Aqueous bromine forms fumaric, and the two di-bromo-succinic acids, and di-bromo-furfurane tetrabromide  $C_8H_2Br_4O$  [111°]. Dilute  $HNO_3$  produces maleic acid.

**Salts.**— $KA'$ .— $NaA'$ .— $AgA'$ .— $BaA'$  4aq (H. a. S.): pearly plates. S. (of  $BaA'$ ) 3:47 at 18°.— $BaA'$  2:4aq (C. a. O.).— $CaA'$  3aq: clumps of prisms. S. (of  $CaA'$ ) 1:07 at 20°.

**Ethyl ether**  $EtA'$  [17°]. (235° i. v.).

**Amide**  $C_8H_4BrO_2(NH_2)$  [145°]; needles (from water).

**Tetrabromide**  $C_8H_2Br_4O_2$ : [173°]; needles (from HOAc).

**Di-bromo-pyromucic acids.** Pyromucic acid combines with bromine forming a tetrabromide which when boiled with alcoholic NaOH forms a mixture of two di-bromo-pyromucic acids ( $\beta$  and  $\delta$ ). ( $\delta$ -bromo-pyromucic acid and a tri-bromopyromucic acid (the latter from tetrabromide of ( $\delta$ -bromopyromucic acid present in the crude bromide). The calcium salt of the ( $\delta$ ) acid is ppd. from dilute (1 in 30) solutions of the mixed acids by  $NH_3$  and  $CaCl_2$ . Of the remaining acids, the ( $\delta$ ) acid is present in very small quantity, while the tri-bromo- acid is very sparingly soluble in hot water (Hill a. Sanger, A. 232, 67; B. 17, 1759; cf. Tönies, B. 11, 1085; 12, 1202; Canzoneri a. Oliveri, G. 14, 177).

**Constitution.**—(Hill a. Sanger, A. 232, 97). Bacyer has proposed for pyromucic acid

The two di-bromo-pyromucic acids would then be

anhydride and Br; formed also by heating the following acid with water.

**Mesa-di-bromo-pyrotartaric acid**

$\text{CO}_2\text{H.CBr.CBrMe.CO}_2\text{H}$ . [194°] and [204°]. S. 81.5 at 13°. From mesaconic acid and Br on warming (Kekulé, *A. Suppl.* 2, 102; Fittig, *A.* 188, 86; 206, 1). Nodules. Heated with  $\text{Na}_2\text{CO}_3\text{Aq}$  it gives propionic aldehyde, two bromo-methacrylic acids,  $\text{CO}_2$ , and HBr. Heated with water it gives propionic aldehyde and bromo-citraconic anhydride.

**Di-bromo-pyrotartaric acid** [102°]. Formed by brominating pyrotartaric acid (Reboul a. Bourgoin, *Bl.* [2] 27, 348).

**Dj-bromo-pyrotartaric acid** [128°]. From propane tri-carboxylic acid and Br (Bischoff a. Emmert, *B.* 15, 1107).

**Tri-bromo-pyrotartaric acid**  $\text{C}_3\text{H}_2\text{Br}_3\text{O}_7$ . From pyrotartaric acid, Br, and water at 120° (Lagermark, *Z.* 1870, 299). Hexagonal prisms; sublimes above 240°. —  $\text{Ag}_2\text{A}'$ .

**TETRA-BROMO-PYROTRITARIC ACID**

$\text{C}_4\text{H}_2\text{Br}_4\text{O}_8$ . **Tetra-bromo-uric acid**. [162°]. Obtained by exposing powdered dry pyrotritaric acid to the vapour of dry bromine at the ordinary temperature. Large colourless crystals. V. sol. alcohol, ether, acetone, acetic acid, chloroform, benzene, and  $\text{CS}_2$ , insol. water and petroleum-ether. The bromine is removed by alkalis and by aniline. By sodium-amalgam in slightly acid solution it is reduced back to pyrotritaric acid. By the action of an excess of bromine at 100° it yields penta-bromo-pyrotartaric acid.

**Tetra-bromide**  $\text{C}_4\text{H}_2\text{Br}_4\text{O}_8$ : [180°]. Formed by dissolving tetra-bromo-pyrotartaric acid in an excess of dry bromine. Small prisms; v. sol. acetic acid, sl. sol. benzene, chloroform, and  $\text{CS}_2$ , insol. water and ligroin. Decomposed by alkalis. Reduced to pyrotritaric acid by sodium amalgam (Dietrich a. Paal, *B.* 20, 1078).

**Penta-bromo-pyrotartaric acid**

$\text{C}_4\text{H}_2\text{Br}_5\text{O}_8(\text{CO}_2\text{H})$ . [c. 197°]. Obtained by heating the tetra-bromo-derivative with excess of bromine at 100°. White glistening crystals. V. sol. ordinary solvents except water and ligroin (Dietrich a. Paal, *B.* 20, 1082).

**TRI-BROMO-PYRROL-(a)-CARBOXYLIC ACID**  $\text{C}_4\text{NHBr}_3(\text{CO}_2\text{H})$ . **Tri-bromo-(a)-carboxypyrrolic acid**. Brown colourless needles. V. sol. alcohol, ether, acetone, sl. sol. hot water, insol. petroleum-ether. The methyl ether is formed by bromination of the methyl ether of pyrrol-(a)-carboxylic acid.

**Methyl ether**  $\text{A'Me}$ : [210°]. Long slender needles, v. sol. ether and hot alcohol, sl. sol. benzene and petroleum-ether, insol. water (Ciamician a. Silber, *B.* 17, 1153).

**Di-bromo-pyrrol di-carboxylic acid**. **Methyl ether**  $\text{C}_4\text{NHBr}_2(\text{CO}_2\text{Me})_2$ . [222°]. From di-methyl pyrrol di-carboxylate and Br (Ciamician a. Silber, *G.* 17, 249). Long white needles; insol. water, sol. ether and hot alcohol. Converted by cold fuming  $\text{HNO}_3$  into  $\text{C}_4\text{H}_2\text{Br}_2\text{NO}_4$  [c. 171°].

**BROMO-PYRRL METHYL KETONE**

$\text{CH}_3\text{CO.C}_4\text{H}_2\text{BrNH}$ . **Pseudo-acetyl-bromo-pyrrol**. [108°]. Long colourless needles; obtained by bromination of pyrrol methyl ketone (Ciamician a. Dennstedt, *B.* 16, 2354).

**Di-bromo-pyrrol methyl ketone**

$\text{CH}_3\text{CO.C}_4\text{HBr}_2\text{NH}$ . [144°]. white needles.

Formed by bromination of pyrrol methyl ketone.

**Tri-bromo-pyrrol methyl ketone**  $\text{C}_6\text{H}_2\text{Br}_3\text{ON}$ .

[179°]. White silky needles. Sol. hot alcohol, ether, and aqueous alkalis, insol. water. Formed by the action of bromine upon pyrrol methyl ketone in aqueous solution (Ciamician a. Silber, *B.* 18, 1765).

**Penta-bromo-pyrrol methyl ketone**

$\text{C}_6\text{H}_2\text{Br}_5\text{ON}$ . [200°]. Small white needles. Formed by bromination of the tri-bromo-derivative dissolved in acetic acid (C. a. S., *B.* 18, 1765) or of pyrrol methyl ketone (C. a. D.).

**BROMO-PYRUVIC ACID**  $\text{C}_3\text{H}_2\text{Br}_2\text{O}_4$ , i.e.

$\text{CH}_2\text{Br.CO.CO}_2\text{H}$ . From pyruvic acid, Br, and water at 100° (Wiechellhaus, *B.* 1, 265). Syrup.

**Di-bromo-pyruvic acid**  $\text{C}_3\text{HBr}_2\text{CO.CO}_2\text{H}$ .

[91°] (W.); [93°] (C.). From pyruvic acid (15g.), water (10g.), and Br (45g.) at 100° (Böttlinger, *B.* 14, 1236; cf. Grimaux, *Bl.* [2] 21, 231; Clermont, *Bl.* [2] 19, 103; Wislicenus, *A.* 148, 208). Monoclinic efflorescent tables (containing 2aq); sol. water and ether. Baryta converts it into tartaric acid. Benzene and conc.  $\text{H}_2\text{SO}_4$  form  $\text{CHBr}_2\text{C}(\text{OH})\text{Ph.CO}_2\text{H}$  (Böttlinger, *B.* 14, 1235). — **Di-bromo-pyruvic acid** (1 mol.), urea (1 mol.) and conc.  $\text{H}_2\text{SO}_4$  form di-bromo-pyruvureide  $\text{C}_4\text{H}_2\text{Br}_2\text{N}_2\text{O}_6$ , whence bromine-water forms tri-bromo-pyruvin  $\text{C}_3\text{Br}_3\text{N}_2\text{O}_5\text{H}$ , a body which is decomposed by cold ammonia into bromoform and ammoniac oxalurate. Ammonia converts di-bromo-pyruvureide into di-bromo-pyruvanide  $\text{C}_4\text{H}_2\text{Br}_2\text{N}_2\text{O}_5$  which is decomposed by boiling baryta-water into  $\text{NH}_3$ , urea, HBr, tartaric acid, and amido-uracil  $\text{C}_4\text{H}_2\text{N}_4\text{O}_6$  (E. Fischer, *A.* 239, 185).

**Tri-bromo-pyruvic acid**  $\text{CBr}_3\text{CO.CO}_2\text{H}$ . [90°], [101°, hydrated]. Formed, together with the preceding, by brominating pyruvic acid (Grimaux, *Bl.* [2] 21, 390). Also from lactic acid and Br. Lamiae resembling naphthalene (containing 2aq); sl. sol. cold water. Decomposed by boiling water into bromoform and oxalic acid.

**Ethyl ether**  $\text{EtA}$ . [97°]. Formed by adding Br to a solution of lactic acid in ether (Klimenko, *J. R.* 8, 125; Wislicenus, *A.* 143, 10).

**DI-BROMO-PYRUVURAMIDE**  $\text{C}_4\text{H}_2\text{N}_2\text{Br}_2\text{O}_5$ .

**Di-bromo-pyruvuramide**. [170°-180°]. From di-bromo-pyruvureide and conc.  $\text{NH}_3\text{Aq}$  in the cold (Fischer, *A.* 239, 191). "Slender needles (from alcohol). V. sol. warm water, but slowly decomposed by boiling water. Decomposed by boiling baryta-water into  $\text{NH}_3$ , urea, HBr and tartaric acid, another portion forming amido-uracil.

**DI-BROMO-PYRUVUREIDE**  $\text{C}_4\text{H}_2\text{Br}_2\text{N}_2\text{O}_6$ .

**Di-bromo-pyruvureide**. From di-bromo-pyruvic acid (q.v.), urea, and conc.  $\text{H}_2\text{SO}_4$  (Fischer, *A.* 239, 188). Granular crystals (from HOAc), v. sl. sol. alcohol, water, and acids; sol. dilute alkalis. Decomposed by boiling alkalis. Decomposed by heat above 280°. Its ammonium and guanidine salts are sl. sol. water.

**TRI-BROMO-PYRUVURIL ANHYDRIDE**

$\text{C}_3\text{H}_2\text{Br}_3\text{N}_2\text{O}_5$ . **Tri-bromo-anhydro-pyruvil**. [180°]. Formed by heating tri-bromo-pyruvic acid and urea at 100° (Grimaux, *A. Ch.* [5] 11, 373). Light needles (from water).

**TRI-BROMO-PYRUVURINE**  $\text{C}_4\text{H}_2\text{Br}_3\text{N}_2\text{O}_5$ , i.e.  $\text{CBr}_3\text{CO.CO.NH.CO.NH}_2$ . **Ureide of tri-bromo-pyruvic acid**. **Tri-bromo-pyruvin**. [247°]

From di-bromo-pyruvureide and excess of bromine-water at 100° or  $\text{HNO}_3$  (S.G. 1.4) (Fischer, A. 239, 189). Glittering plates, m. sol. boiling water and alcohol, v. sl. sol. ether. Decomposed even by cold alkalis into bromoform and ammonium oxalurate.

(B. 2)-BROMO-QUINOLINE  $\text{C}_8\text{H}_6\text{BrN}$  i.e.  $\text{C}_8\text{H}_5\text{Br}(\text{C}_6\text{H}_5\text{N})$ . Benz-bromo-quinoline. (278°). Liqui. Volatile with steam. Prepared by heating *p*-bromo-aniline with glycerin, nitrobenzene and  $\text{H}_2\text{SO}_4$ ; the yield is 80 p.c.

Salts.— $\text{B}^+\text{HCl}^-$ : small white needles.— $(\text{B}^+\text{HCl})_2\text{PtCl}_6^-$ : microscopic needles (La Coste, B. 15, 558).

Bromo-quinoline  $\text{C}_8\text{H}_6\text{BrN}$ . (270°). Yellowish oil. Prepared by bromination of quinoline. Perhaps identical with the preceding.

Salts.— $\text{B}^+\text{HCl}^-$ : monoclinic prisms.— $(\text{B}^+\text{HCl})_2\text{PtCl}_6^-$ : fine orange-red needles.

Methylo-iodide  $\text{C}_8\text{H}_6\text{BrNMeI}$ . By the action of  $\text{Ag}_2\text{O}$  on an aqueous solution of the iodide, a strongly alkaline solution of the hydrate is produced ( $\text{C}_8\text{H}_6\text{BrNMeOH}$ ); this is transformed on standing or warming, by splitting off  $\text{H}_2\text{O}$ , into the much more stable methylo-oxide.

Methylo-oxide ( $\text{C}_8\text{H}_6\text{BrNMeO}$ ). [147°]. This is also formed by the action of  $\text{KOH}$  on the iodide. Colourless needles. Soluble in hot alcohol, sparingly in cold, very slightly soluble in water and ether. Combines with acids very slowly (La Coste, B. 14, 915; 15, 188).

(Py. 1 or 2)-Bromo-quinoline  $\text{C}_8\text{H}_6\text{BrN}$   $\begin{matrix} \text{CH:CH} \\ | \\ \text{N:CH} \end{matrix}$  or  $\text{C}_8\text{H}_6\text{BrN}$   $\begin{matrix} \text{CH:CH} \\ | \\ \text{N:CH} \end{matrix}$ . (274° uncor.). Formed, together with propyl bromide, propylene bromide, quinoline hydrobromide, &c., by heating the propylo-bromide of quinoline-di-bromide to 170°–190°. Prepared by heating to 180° the hydrobromide of quinoline-di-bromide:  $\text{C}_8\text{H}_6\text{Br}_2\text{N.HBr} = \text{C}_8\text{H}_5\text{Br}_2\text{N.HBr} + \text{HBr}$ ; the quinoline-di-bromide is formed by the action of bromine on an ethereal solution of quinoline. Oil of aromatic smell resembling quinoline. On oxidation with  $\text{KMnO}_4$  it yields oxaloxyl-anthranilic acid  $\text{C}_8\text{H}_6(\text{CO}_2\text{H})_2\text{NH.CO.CO.H}$  and bromo-pyridine-di-carboxylic acid  $\text{C}_8\text{H}_6\text{BrN}(\text{CO}_2\text{H})_2$ .

Salts.— $\text{B}^+\text{HCl}^-$ : needles or tables; sublimes without melting.— $\text{B}^+\text{HBr}^-$ : four-sided tables or prisms; sublimes at c. 130° without melting; sol. alcohol, sl. sol. cold water.— $\text{B}^+\text{HNO}_3^-$ : [180° uncor.]; small concentric prisms.— $\text{B}^+\text{H}_2\text{SO}_4^-$ : [183° uncor.]; small needles; dissociated by water.— $\text{B}^+\text{H}_2\text{CrO}_4^-$ : [145°]; sparingly soluble flat yellow prisms (from hot water).— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6^-$ : small orange-yellow needles.— $\text{B}^+\text{AgNO}_3^-$ : [173°]; needles (Claus a. Colischonn, B. 19, 2763).

(B. 1.4)-Di-bromo-quinoline  $\text{CH:CH} > \text{C}_8\text{H}_4\text{N}$ . [128°]. (a)-Di-bromo-quinoline.  $\text{CH:CH} > \text{C}_8\text{H}_4\text{N}$ . [128°]. (a)-Di-bromo-quinoline.

Formation.—1. By bromination of quinoline by heating the hydrochloride with bromine at 180° (La Coste, B. 14, 917; 15, 191).—2. By heating di-bromo-aniline [1:4:5] with a mixture of glycerine, nitrobenzene and  $\text{H}_2\text{SO}_4$  (Metzger, B. 17, 186).

Properties.—Distills without decomposition. Volatile with steam. Long white needles. Almost

insol. water, v. sol. alcohol, ether, benzene and aqueous acids.

Salts.— $\text{B}^+\text{HCl}^-$ : small needles.— $\text{B}^+\text{H}_2\text{Cl}_2\text{PtCl}_6^-$ : fine yellow needles.— $\text{B}^+\text{H}_2\text{CrO}_4^-$ : orange-red microcrystalline powder, decomposed by water into the base and  $\text{CrO}_3$ . The pierate forms long yellow needles, decomposed by water.

Methylo-iodide  $\text{B}^+\text{MeI}$ : Slender red needles. Sol. hot water, insol. ether and cold alcohol.

Methylo-oxide  $\text{B}^+\text{Me}_2\text{O}$ . Formed by the action of  $\text{NaOH}$  on the iodide. Microscopic needles.

(B. 2, 4)-Di-bromo-quinoline  $\text{C}_8\text{H}_4\text{Br}_2(\text{C}_6\text{H}_5\text{N})$ . [101°]. Slender colourless needles. Volatilises undecomposed. Formed by heating di-bromo-aniline with glycerin, nitrobenzene and  $\text{H}_2\text{SO}_4$ . ( $\text{B}^+\text{HCl})_2\text{PtCl}_6$  (La Coste, B. 15, 559).

Di-bromo-quinoline (probably B. 2: Py. 1)  $\text{C}_8\text{H}_4\text{Br}_2\text{N}$ . [124° uncor.]. Formed by the action of bromine (2 mols.) upon quinoline-(B. 2)-sulphonic acid (1 mol.) in cold aqueous solution. Long colourless needles (from ether). Sublimable. It is oxidised by  $\text{KMnO}_4$  to bromo-pyridine-di-carboxylic acid [165°] (Claus a. Küttner, B. 19, 2884).

Di-bromo-quinoline tetrahydride  $\text{C}_8\text{H}_6\text{Br}_2\text{N}$ . [66° uncor.]. Formed by reduction of tetra-bromo-quinoline with sodium amalgam. Colourless tables. Volatile with steam. Sol. alcohol and ether, insol. water.

Salts.— $\text{B}^+\text{HCl}^-$ : [75°], acicular crystals.— $(\text{B}^+\text{HCl})_2\text{PtCl}_6$ : 2aq: yellow crystalline powder.— $\text{B}^+\text{HNO}_3^-$ : [189°]: prisms.— $\text{B}^+\text{H}_2\text{SO}_4^-$ : white plates, decomposes at 246° uncor.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4^-$ : colourless tables, decomposes at 171° uncor. (Claus a. Istel, B. 15, 822).

Tri-bromo-quinoline  $\text{C}_8\text{H}_3\text{Br}_3\text{N}$ . [170° uncor.]. Formed by the action of bromine (3 mols.) upon an aqueous solution of quinoline-(B. 2)-sulphonic acid (1 mol.) at 100°. Long silky needles. Sl. sol. cold ether (Claus a. Küttner, B. 19, 2885).

Tri-bromo-quinoline  $\text{C}_8\text{H}_3\text{Br}_3\text{N}$ . [175°]. From quinoline and  $\text{Br}$  (Lubavin, A. 155, 318). Silky needles; v. sol. hot alcohol. Possibly identical with the preceding.

Tri-bromo-quinoline  $\text{C}_8\text{H}_3\text{Br}_3\text{N}$ . [198° uncor.]. Formed by the action of bromine upon an aqueous solution of quinoline-(B. 4)-sulphonic acid at 100°. White felted silky needles. V. sol. ether and hot alcohol. Sublimable (Claus a. Küttner, B. 19, 2882).

Tetra-bromo-quinoline  $\text{C}_8\text{H}_2\text{Br}_4\text{N}$ . [119° uncor.]. Long colourless needles or thick prisms. Insoluble in water. Formed by bromination of quinoline in  $\text{CS}_2$  (Claus a. Istel, B. 15, 820).

Hexa-bromo-quinoline  $\text{C}_8\text{HBr}_6\text{N}$ . [90°]. From pyridine (2, 3)-di-carboxylic acid,  $\text{Br}$ , and water (Weidel, A. 173, 93). Needles (from alcohol). Reduced to quinoline by sodium amalgam.

(B. 4)-BROMO-QUINOLINE (B. 1)-CAP. BOXYLIC ACID  $\text{C}_8\text{H}_4\text{BrN}(\text{CO}_2\text{H})_2$ . [275°]. From bromo-amido-benzoic acid  $\text{C}_8\text{H}_4\text{Br}(\text{NH}_2)\text{CO}_2\text{H}$  [1:2:4] (10g.), glycerin (22.5g.), o-nitro-phenol (6g.), and  $\text{H}_2\text{SO}_4$  (20g.) by heating for 5 hours at 160° (Lellmann a. Alt, A. 237, 813). White powder, v. sl. sol. water and ether, sl. sol. hot alcohol. Salt.— $(\text{HA})_2\text{H}_2\text{PtCl}_6$  4aq.

( $\alpha$ )-BROMO-QUINOLINE-SULPHONIC ACID  $C_8H_6(Br)N(SO_3H)$ . S. 0.08 at 22°; 9 at 100°. Short thin needles. Sl. sol. alcohol. Formed together with the  $\beta$ -acid by sulphonating bromo-quinoline.

Salts.— $A_2Mn4aq$ : small yellow needles.— $A_2Ag$ : spangles or needles.— $A_2K$ : short prisms, S. 1.37 at 17°.— $A_2NH_4$ : felted needles.— $A_2Ba$ : nearly insoluble crystalline pp.— $A_2Mg$  10aq: colourless plates.— $A_2Zn$  4aq: thin colourless needles (La Coste, B. 15, 1910).

( $\beta$ )-Bromo-quinoline-sulphonic acid  $C_8H_6N(Br)(SO_3H)$ . S. 15 at 22°; 2.75 at 100°. Short thick needles (containing aq). Formed together with the ( $\alpha$ )-acid by sulphonation of bromo-quinoline.

Salts.— $A_2K$  1½aq: large tables, S. 17.25 at 22°.— $A_2Ag$ : colourless needles.— $A_2Ba$  2aq: sparingly soluble needles.— $A_2Mg$  9aq: small needles.— $A_2Zn$  9aq: six-sided tables.— $A_2Mn$  6aq: colourless tables (La Coste, B. 15, 1915).

**BROMO-QUINONE**  $C_8H_6BrO_2$ . [56°]. Formed by oxidising bromo-hydroquinone with  $Fe_2Cl_6$  (Sarauw, A. 209, 106). Groups of needles, v. sol. alcohol, ether, and benzene, sl. sol. hot water. Ammonia gives a green colouration, turning black on warming.

**Di-bromo-quinone**  $C_8H_4Br_2O_2$ . [188°]. Formed by oxidation of di-bromo-hydroquinone (S.; Benedikt, M. 1, 346). Small golden crystals, insol. water, sol. alcohol, ether, and benzene. Boiling KOHAq gives di-bromo-di-oxy-quinone (dibromanilic acid).

**Di-bromo-quinone**  $C_8H_4Br_2O_2$ . [76°].

**Formation.**—Di-bromo-*p*-diazophenol,

$C_6H_3Br_2 \cdot \begin{smallmatrix} O \\ \diagup \diagdown \\ N \end{smallmatrix}$  is converted by a boiling solution of calcium chloride into di-bromo-hydroquinone,  $C_6H_3Br_2(OH)_2$ . This solution is mixed with  $Fe_2Cl_6$  and distilled, when the quinone passes over. The yield is small.

**Properties.**—Long, extremely slender needles, sol. in alcohol, ether,  $CHCl_3$ ,  $CS_2$ , benzene, and alkalis. Pungent. May be sublimed (Böhmer, J. pr. 132, 465).

**Di-bromo-quinone**  $C_8H_4Br_2O_2$ . [122°]. From tri-bromo-phenol and fuming  $HNO_3$  at 0° (Levy a. Schultz, A. 210, 158). Yellow laminae (from dilute alcohol).

**Di-bromo-quinone** [88°]. From quercite and  $HBrAq$  at 160° (Prunier, A. Ch. [5] 15, 67). Three di-bromo-quinones are indicated by theory.

**Tri-bromo-quinone**  $C_8H_3Br_3O_2$ . [147°]. Formed by oxidising tri-bromo-hydroquinone in dilute alcoholic solution (Sarauw, A. 209, 120). Golden leaflets (from alcohol); sol. alcohol, ether, and benzene. Alkalis give a green colouration, followed by separation of red prisms. Boiling conc.  $NaOH$  gives di-bromo-di-oxy-quinone and tri-bromo-hydroquinone. A tri-bromo-quinone [108°] is got by heating quercite with  $HBr$  (P.). A tri-bromo-quinone is also formed by reduction of tetra-bromo-quinone (Stenhouse, A. Symp. 8, 20; cf. Herrmann, B. 10, 110).

**Tetra-bromo-quinone**  $C_8Br_4O_2$ . *Bromanil*.

**Formation.**—1. By treating phenol with  $Br$  and  $I$  (Stenhouse, C. J. 23, 10).—2. By boiling picric acid with  $Br$  and water (Stenhouse, A. 91, 807).—3. From quinone and  $Br$  (Sarauw, B. 12, 680, A. 209, 126).—4. A product of the action of  $Br$

and water on benzoic acid (Hübner, A. 143, 255), and on proteids (Hlasiwetz a. Habermann, A. 159, 820).—5. From tri-bromo-phenol and  $HNO_3$  (Losanitsch, B. 15, 474).—6. From di-oxy-di-hydro-terephthalic (succinyl-succinic) acid and  $Br$  (Herrmann, A. 211, 341).—7. From (1,3,5,4)-bromo-di-nitro-phenol by heating with  $Br$  (Ling, C. J. 51, 147).

**Properties.**—Golden laminae (from  $HOAc$ ); sublimes as sulphur-yellow crystals. Insol. water, m. sol. boiling alcohol, sl. sol. ether.  $HIAq$  reduces it to tetra-bromo-hydroquinone. Potash forms a greenish-black solution turning purple.

**Tetra-bromo-ortho-quinone**  $C_8Br_4O_2$ . [1:2:3:4:5:6]. [151°]. Obtained by oxidation of tetra-bromo-pyrocatechin in acetic acid solution with  $HNO_3$ . It can also be prepared directly from pyrocatechin by adding bromine (10 to 12 pts.) to a boiling solution of the latter (1 pt.) in acetic acid (20 pts.). Dark-red thick prisms, tables, or transparent plates. V. sol. alcohol, ether, acetic acid, and benzene, sl. sol. petroleum spirit. It is a powerful oxidising agent, being readily reduced to tetra-bromo-pyrocatechin. With aniline it gives a compound which crystallises in bluish-black glistening plates or thick needles [173°] (Zincke, B. 20, 1776).

#### DI-BROMO-QUINONE-CHLORIMIDE

$C_8H_4Br_2 \cdot \begin{smallmatrix} NCl \\ \diagup \diagdown \\ O \end{smallmatrix}$  [2:6:4]. [80°] Long yellow

prisms. Prepared by adding a solution of chloride of lime to an acidified solution of di-bromo-amido-phenol [2:6:4:1] (Möhlau, B. 16, 2845).

#### DI-BROMO-QUINONE-PHENOL-IMIDE

$N \cdot \begin{smallmatrix} C_6H_4OH \\ \diagup \diagdown \\ C_8H_4Br_2O \end{smallmatrix}$  [4:2:6:1].

**Formation.**—1. By adding di-bromo-quinone chlorimide to an alkaline solution of phenol.—2. By oxidising an alkaline solution of di-bromo-amido-phenol [2:6:4:1] and phenol with  $K_2Cr_2O_7$ .

**Properties.**—Dark red prisms with metallic reflection. Sol. alcohol, ether and acetic acid with a magenta-red colour; insol. water.

**Reactions.**—On heating with  $HCl$  it is split up into quinone and di-bromo-amido-phenol. On reduction it yields di-bromo-di-oxy-di-phenyl-

amine  $HN \cdot \begin{smallmatrix} C_6H_4OH \\ \diagup \diagdown \\ C_8H_4Br_2OH \end{smallmatrix}$ .

Sodium salt  $C_8H_4Br_2ON(ONa)$ : long blue prisms with golden-green reflection. Soluble in water and alcohol with a blue colour. Heated with an excess of aqueous  $NaOH$  the blue colour changes to red, but reappears on cooling (Möhlau, B. 16, 2845).

**BROMO-RESORCIN**  $C_6H_3Br(OH)_2$ . [91°]. Formed by boiling bromo-di-oxy-benzoic acid with water for some hours (Zehenter, M. 8, 293). Groups of needles; v. sol. water and ether, m. sol. alcohol.  $Fe_2Cl_6$  colours the aqueous solution bluish-violet, a red pp. being subsequently formed. Heated with water,  $K_2CO_3$ , and  $SnCl_2$  it gives resorcin and di-oxy-benzoic acid.

**Bromo-resorcin. Di-propyl derivative**  $C_8H_3Br(OPr)_2$ . [71°]. Formed by brominating di-propyl-resorcin (Kariof, B. 13, 1679). Colourless silky needles; may be sublimed. V. sol. alcohol and  $HOAc$ ; sl. sol. water.

**Di-bromo-resorcin**  $C_6H_2Br_2(OH)_2$ . [93°]. Formed, together with 'di-bromo-mono-resorcin phthalein,' by heating tetra-bromo-fluorescein (eosin) with dilute  $NaOH$  at 140° (Baeyer, A. 183, 57; Hofmann, B. 8, 64). Formed also by boiling di-bromo-(1,3,2)-di-oxy-benzoic acid with water (Zehenter, M. 2, 478; 8, 293). Needles (from water); m. sol. hot water, v. e. sol. alcohol and ether.  $Fe_2Cl_3$  gives a transient violet colour.

**Di-methyl ether**  $C_6H_2Br_2(OMe)_2$ . [141°]. Slender needles. Insol. water, sol. alcohol and ether. Prepared by bromination of the dimethyl-ether of resorcin (Tiemann a. Parrisius, B. 13, 2365; cf. Honig, B. 11, 1041).

**Di-bromo-resorcin**  $C_6H_2Br_2(OH)_2$ . [112°]. From Br and resorcin in  $CS_2$  (Zehenter, M. 8, 293). Colourless needles (containing aq) (from water); m. sol. hot water.  $Fe_2Cl_3$  gives a blue colour followed by a dark pp.

**Tri-bromo-resorcin**  $C_6HBr_3(OH)_2$ . [104°] (Typke, B. 10, 1578). From resorcin, Br, and water (Hlasiwetz a. Barth, A. 130, 357), or Br, and  $HOAc$  (Benedikt, M. 4, 227). Formed also by heating penta-bromo-resorcin with aldehyde or formic acid (Claassen, B. 11, 1439). Small needles; sl. sol. water, v. sol. alcohol.

**Mono-acetyl derivative**  $C_6HBr_3(OH)(OAc)$ . [114°]. From mono-acetyl-resorcin and Br (C); sol. hot water.

**Di-acetyl derivative**  $C_6HBr_3(OAc)_2$ . [108°]. From penta-bromo-resorcin and  $Ac_2O$ . Sol. hot water.

**Mono-methyl ether**  $C_6HBr_3(OH)(OMe)$ . [104°]. From mono-methyl-resorcin and Br. Slender white needles, sol. alcohol and ether, insol. water (Tiemann a. Parrisius, B. 13, 2364).

**Tetra-bromo-resorcin**  $C_6Br_4(OH)_2$ . [163°]. (C); [167°] (B). Formed by treating penta-bromo-resorcin with  $H_2SO_4$  (Claassen, B. 11, 1440; Benedikt, M. 1, 366). Small needles (from alcohol).

**Di-acetyl derivative**  $C_6Br_4(OAc)_2$ . [169°]; v. sol. hot water.

**Penta-bromo-resorcin**  $C_6Br_5(OH)(OBr)$ ? [114°]. Formed by adding an aqueous solution of resorcin to a cooled mixture of Br and water (Stenhouse, A. 163, 184). Dimetric crystals,  $a:c = 6076:1$ . V. sl. sol. water. Alcoholic  $AgNO_3$  pps. more than two-thirds of its Br. At 160° it splits up into bromine and tri-bromo-resoquinone  $C_6HBr_3O_2$  (Liebermann a. Dittler, B. 5, 1090; A. 169, 256). Converted into tri-bromo-resorcin by conc.  $HCl$ ,  $H_2S$ ,  $SnCl_2$ , warm alcohol, aldehyde, or formic acid (Benedikt, M. 1, 351; Claassen, B. 11, 1433). Boiling  $Ac_2O$  gives di-acetyl-tri-bromo-resorcin. Aniline forms tri-bromo-aniline and tri-bromo-resorcin; phenol acts similarly (Benedikt, B. 11, 2168). Boiling dilute  $KOH$  produces bromoform.

**Hexa-bromo-resorcin**  $C_6Br_6(OBr)_2$ ? [136°]. S.G. 1.823-1.88. Prepared by heating tetra-bromo-resorcinol with excess of bromine. Monoclinic crystals:  $a:b:c = 983:1:1.687$ ;  $\beta = 85^\circ 36'$ . Decomposed by alcohol forming tetra-bromo-resorcin (Benedikt, M. 1, 365).

**TRI-BROMO-RESOQUINONE**  $C_6HBr_3O_2$  or  $C_6H_2Br_3O_4$ . Formed by heating penta-bromo-resorcin at 160° (Liebermann a. Dittler, B. 5, 1090). Orange needles; insol. water, v. sol. alcohol and ether. At 230° it gives off Br

leaving amorphous  $C_6H_2Br_3O_4$ . Reduced by Sn and  $HCl$  to tetra-bromo-tetra-oxy-diphenyl (Benedikt, M. 1, 350; B. 11, 2170).

**DI-BROMO-RESORCIN-PHTHALEIN** so-called  $C_6H_2Br_2O_4$ , i.e.  $CO_2H.C_6H_2.CO_2C_6HBr_2(OH)_2$ , *Di-bromo-di-oxy-benzoyl-benzoic acid*. [220°]. Formed, together with di-bromo-resorcin, by heating tetra-bromo-fluorescein with dilute  $NaOH$  (Baeyer, A. 183, 56). Plates, v. sl. sol. water.

**BROMO-RETENE** v. RETENE.

**BROMO-ICINELAIDIC ACID**  $C_{18}H_{32}BrO_4$ . From the dibromide of ricinelaic acid and alcoholic  $KOH$ . Oil. Alcoholic  $KOH$  forms an acid [71°] (Ulrich, Z. 1867, 549).

**BROMO-ICINOLEIC ACID**  $C_{18}H_{32}BrO_4$ . From ricinoleic acid by successive treatment with Br and alcoholic  $KOH$  (Ulrich, Z. 1867, 546). Oil; converted by alcoholic  $KOH$  into ricin-stearolic acid  $C_{18}H_{32}O_4$ .

**Di-bromo-ricinoleic acid**  $C_{18}H_{32}Br_2O_4$ . From ricin-stearolic acid and Br. Oil.

**BROMO-ROSANILINE** v. ROSANILINE.

**TETRA-BROMO-ROSOLIC ACID**  $C_{20}H_{12}Br_4O_4$ . From Br and rosolic acid in  $HOAc$  (Graebe a. Caro, A. 179, 201). Lustrous green plates, insol. water. Its alkaline solutions are violet.— $A''Ag_2$ : dark violet pp.

**Ethyl ether**  $A''Et_2$ : [110°-115°], soluble in alcohol, ether, and benzene, insoluble in water (Ackermann, B. 17, 1627).

**BROMO-ROSOQUINONE**  $C_{12}H_4Br_2O_2$  i.e.

$C_6H_2Br_2-O$  | (2). Red and steel-blue crystals.  
 $C_6H_2Br_2-O$

Prepared by the oxidation of tetra-bromo-phenolphthalein (5 pts.) dissolved in  $H_2SO_4$  (250 pts.) with a mixture of  $HNO_3$  (5 pts.) and  $H_2SO_4$  (50 pts.).

**Bromo-resoquinone**  $C_{12}H_4Br_2O_2$  i.e.

$C_6H_2Br_2-OH$  | (2). Tetra-bromo-di-oxy-diphenyl.  
 $C_6H_2Br_2-OH$

[264°]. Sublimable. Prepared by the reduction of the corresponding quinone (Baeyer a. Schraube, B. 11, 1301).

**BROMO-SALICYLIC ACID** v. BROMO-O-OXY-BENZOIC ACID.

**BROMO-SALICYLIC ALDEHYDE** v. BROMO-O-OXY-BENZOIC ALDEHYDE.

**BROMO-STEARIC ACID**  $C_{18}H_{31}BrO_2$ . [41°]. S.G. 1.0653. From stearic acid (7 pts.), bromine (4 pts.), and water at 135° (Oudemans, J. pr. 89, 195). Crystalline mass, insol. water, v. sol. alcohol and ether. The silver salt heated with water forms stearic acid  $C_{18}H_{37}O_2$ .

**Di-bromo-stearic acid**  $C_{18}H_{31}Br_2O_4$ . From oleic acid and Br (Overbeck, A. 140, 42). Oil. Alcoholic  $KOH$  forms bromo-oleic and stearolic acids. Moist  $Ag_2O$  gives oxy-oleic acid  $C_{18}H_{31}O_4$  and di-oxy-stearic acid  $C_{18}H_{29}O_6$ .

**Di-bromo-stearic acid**  $C_{18}H_{31}Br_2O_4$ . [27°]. From elaidic acid and Br. Reduced to elaidic acid by sodium amalgam.

**Tri-bromo-stearic acid**  $C_{18}H_{33}Br_3O_4$ . From bromo-oleic acid and Br. Oil.

**Tetra-bromo-stearic acid**  $C_{18}H_{32}Br_4O_4$ . [70°]. From stearolic acid and Br. Laminæ (from alcohol).

**BROMO-STILBENE** v. BROMO-DI-PHENYL-ETHYLENE.

**BROMO-STREYCHNINE** *v.* STREYCHNINE.

**$\alpha$ -BROMO-STYRENE**  $\text{C}_8\text{H}_7\text{Br}$  *i.e.*  $\text{C}_6\text{H}_5\text{CH}:\text{CHBr}$ . *Bromo-phenyl-ethylene*. Formed by boiling styrene dibromide with alcoholic KOH or by heating it with water at 190° (Glaser, *A.* 154, 168; Radziszewski, *B.* 6, 493). Heavy pungent oil; decomposed by distillation. Converted by heating with water into phenyl-acetic aldehyde (Erlenmeyer, *B.* 14, 323).

**$\alpha$ -Bromo-styrene**  $\text{C}_8\text{H}_7\text{Br}$   $\text{C}_6\text{H}_5\text{CH}:\text{CHBr}$  [7°]. (220° i.v.).

*Formation*.—1. From styrene dibromide and alcoholic KOAc at 160° (Zincke, *A.* 216, 290).—2. By boiling  $\alpha\beta$ -di-bromo-phenyl-propionic acid with water (Barisch, *J. pr.* [2] 20, 179; Fittig a. Binder, *A.* 195, 141).—3. From bromo-oxy-phenyl-propionic acid and water at 200° (t.).

*Properties*.—Oil, with pleasant odour of hyacinths. May be distilled. Does not readily give up its Br. Converted into acetophenone by heating with water at 180° (Friedel a. Bilsuhn, *Bl.* [2] 32, 614).

**Di-bromo-styrene**  $\text{C}_8\text{H}_6\text{Br}_2$  (254°). From tri- $\alpha\beta$ -bromo- $\beta$ -phenyl-propionic acid and water at 100° (Kinnicut a. Palmer, *Am.* 5, 381). Oil.

**Tri-bromo-styrene**  $\text{C}_8\text{H}_5\text{Br}_3$ . From the preceding and Br. Oil (K. a. P.).

**BROMO-STYRENE DIBROMIDE** *v.* DI-BROMO-ETHYL-BENZENE.

**BROMO-SUBERIC ACID**  $\text{C}_{10}\text{H}_{16}\text{Br}(\text{CO}_2\text{H})_2$  [103°]. Prepared, together with di-bromo-suberic acid, by the action of bromine and phosphorus on suberic acid. Crystalline powder. Sol. alcohol and ether. By alcoholic KOH it gives suberic acid (Gantner a. Hell, *B.* 15, 142).

**Di-bromo-suberic acid**  $\text{C}_{10}\text{H}_{14}\text{Br}_2(\text{CO}_2\text{H})_2$  [173°]. Formed by bromination of *n*-suberic acid. Glistening needles. V. sol. alcohol, ether, and hot water, v. sl. sol. benzene, chloroform, ligroin, and cold water. By heating with alcoholic KOH it gives di-ethoxy-suberic acid together with a small quantity of suberic acid  $\text{C}_8\text{H}_{16}(\text{CO}_2\text{H})_2$  (Hell a. Rempel, *B.* 18, 813).

**BROMO-SUCCINIC ACID**  $\text{C}_4\text{H}_5\text{BrO}_4$  *i.e.*  $\text{CO}_2\text{H}.\text{CH}_2.\text{CHBr}.\text{CO}_2\text{H}$ . [160°]. S. 19-2 at 15-5°.

*Formation*.—1. By heating succinic acid (5g.) with Br (2½ c.c.) and water (40 c.c.) at 120° (Kekulé, *A.* 117, 125; Carius, *A.* 129, 6; Hell, *B.* 14, 892).—2. From succinic acid (5g.), Br (2½ c.c.) and chloroform (5 c.c.) at 160° (Orlowsky, *J. R.* 9, 277).—3. From succinic ether and Br (Schacherl, *B.* 14, 637).—4. By the action of HBr on fumaric, tartaric, malic, and racemic acids (Kekulé, *A.* 130, 21; Fittig, *A.* 188, 88; Anschütz a. Bennert, *B.* 15, 613).—5. By decomposing its bromide with water (Volhard, *A.* 242, 153).

*Properties*.—Small prisms, v. sol. water. Its silver salt rapidly decomposes. Moist  $\text{Ag}_2\text{O}$  gives malic acid. Sodium-amalgam produces succinic acid. Boiling water slowly forms fumaric acid.

**Anhydride**  $\text{C}_4\text{H}_3\text{BrO}_3$  [313°]. (137°) at 11 mm. From the acid and  $\text{AsCl}_3$  at 100° (A. a. B.). Decomposed by heat into HBr and maleic anhydride.

**Methyl ether**  $\text{Me}_2\text{A}''$ . (c. 134°) at 30 mm. **Ethyl ether**  $\text{Et}_2\text{A}''$ . (226°). Inflames the skin. Cold aqueous or alcoholic  $\text{NH}_3$  convert

it into fumaramide. Aqueous  $\text{NH}_3$  at 110° gives asparagine (Körner a. Menozzi, *G.* 17, 171).

**Bromide**  $\text{C}_4\text{H}_4\text{Br}(\text{CO}_2\text{Br})_2$ . Formed by adding Br (1100g.) gradually to a mixture of succinic anhydride (300g.) and amorphous P (36g.) (Volhard, *A.* 242, 151).

**$\alpha$ -Di-bromo-succinic acid**  $\text{CO}_2\text{H}.\text{CHBr}.\text{CHBr}.\text{CO}_2\text{H}$ . S. 2-04 at 100°.

*Formation*.—By heating succinic acid (42g.) with Br (11 c.c.) and water (12 c.c.) at 180° (Kekulé, *A.* 117, 123; *Suppl.* 1, 131; Bourgoin, *Bl.* [2] 19, 148).—2. From fumaric acid and Br (K. a. Baeyer, *B.* 18, 676).

*Properties*.—Opaque prisms, sl. sol. cold water, v. sol. alcohol and ether.

*Reactions*.—1. *Sodium amalgam* reduces it to succinic acid.—2. *Boiling water* converts the sodium salt into hydro-sodic bromo-maleate, the Ba salt into hydro-baric bromo-maleate and barium racemate, the silver salt into inactive tartaric acid, and the acid itself into HBr and bromo-maleic acid.—3. *Water* at 140° gives iso-bromo-maleic acid.—4.  $\text{NH}_3$  gives bromo-amido-succinic acid.—5. *Reduction* in acid solution gives fumaric acid (Ossipoff, *Bl.* [2] 34, 346).—6. Heating with *thio-urea* gives fumaric acid (Nencki a. Sieber, *J. pr.* [2] 25, 79).

*Salts*.— $(\text{NH}_4)_2\text{A}''$ .— $\text{Na}_2\text{A}''$  4aq.— $\text{Ag}_2\text{A}''$ .— $\text{CaA}''$  2aq.

**Mono-methyl ether**  $\text{MeHA}''$ : decomposes about 215°.— $\text{NaMeA}''$  4aq (Claus, *B.* 15, 1844).

**Mono-ethyl ether**  $\text{EtHA}''$  [275°].— $\text{KEtA}''$  1½aq.  $\text{NaEtA}''$  2aq.— $\text{AgEtA}''$  1½aq (C.).

**Methyl ether**  $\text{Me}_2\text{A}''$ . [62°]. Mono-symmetrical crystals. Prepared by the action of bromine on methyl fumarate.

**Ethyl ether**  $\text{Et}_2\text{A}''$ . [58°]. (K. a.); [68°] (Lehrfeld, *B.* 14, 1820). Rhombic crystals. Prepared by the action of bromine on ethyl fumarate. On heating to 170° it decomposes into bromo-maleic ether and HBr (Anschütz, *B.* 12, 2281). Aniline converts it into  $\text{C}_6\text{H}_5\text{N}(\text{Ph})_2(\text{CO}_2\text{Et})_2$  [145°] (Lopatine, *C. R.* 105, 250).

**Methyl-ethyl ether**  $\text{MeEtA}''$  [63°] (C.).

**Chloride**  $\text{C}_4\text{H}_3\text{Br}_2\text{O}_3\text{Cl}_2$  [63°]. From Br and succinyl chloride or fumaryl chloride (Perkin a. Duppa, *C. J.* 13, 102; K.).

**Amic acid**  $\text{CO}_2\text{H}.\text{C}_6\text{H}_4.\text{Br}.\text{CO}.\text{NH}_2$ . Unstable crystals (C.; Michael a. Wing, *Am.* 6, 421).

**Anilide (?)**

**NHPh. SO**  $\text{CHBr}.\text{CHBr}.\text{CO}.\text{NHPh}$ . From the anilide of fumaric acid and bromine (Anschütz a. Wirtz, *A.* 239, 138; *Am.* 9, 240). White powder, does not melt below 300°.

**Phenyl-imide**  $\text{Ph}:(\text{C}_6\text{O}_2):\text{C}_4\text{H}_3\text{Br}_2$  [159°]. From the phenyl amide of maleic acid (maleanil) in chloroform by adding Br (A. a. W.).

**Iso- (or allo) di-bromo-succinic acid**

(cf. Anschütz, *A.* 239, 181). [160°].

*Formation*.—1. From maleic acid and Br (Kekulé, *A.* *Suppl.* 2, 89).—2. Together with its isomeride, by heating bromo-maleic anhydride with HBr, or succinic acid with water and Br at 140° (Franchimont, *B.* 6, 199; Bourgoin, *B.* 6, 624).—3. From (3)-bromo-pyromucic acid, Br. and water (Hill a. Sanger, *A.* 232, 53).

**Preparation.**—By dissolving its anhydride in water (Pictet, B. 18, 1870).

**Properties.**—Large crystals; more soluble in water than its isomeride. At 180° it gives off HBr, bromo-fumaric acid being formed.

**Reactions.**—1. Boiling water converts the acid and its Ba salt into bromo-maleic acid, but the Ag salt into racemic acid.—2. Moist Ag<sub>2</sub>O gives pyruvic acid (Beilstein'a. Wiegand, B. 15, 1499).—3. Sodium amalgam produces succinic acid.

**The Di-methyl ether** A'Me<sub>2</sub> and the **Di-ethyl-ether** A'Et<sub>2</sub> are oily liquids, insol. water (Pictet, B. 18, 1870).

**Anhydride** C<sub>2</sub>H<sub>2</sub>Br<sub>2</sub>.CO<sub>2</sub> [32°]. Prepared by heating maleic anhydride with bromine at 100° (Pictet, B. 13, 1669). Colourless tables. Has a great affinity for water, with which it forms iso-dibromo-succinic acid. On heating to 100° it evolves HBr forming bromo-maleic anhydride.

**Tri-bromo-succinic acid** CO<sub>2</sub>H.CBr<sub>2</sub>.CHBr.CO<sub>2</sub>H. [137°]. From bromo-maleic or bromo-fumaric acid and Br (Petri, A. 195, 69). Deliquescent needles; boiling water converts it into di-bromo-acrylic acid.

**BROMO-SULPHI-BENZOIC ACID** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>H)(CO<sub>2</sub>H) [4: 2 or 3: 1]. [238°-245°]. From C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>Cl)CO<sub>2</sub>H by treatment with alcohol and zinc-dust (C. Böttinger, A. 191, 24).—BaA''—BaH<sub>2</sub>A'' 2aq.—CaH<sub>2</sub>A'' 8aq.

**BROMO-SULPHI-BENZOIC ALDEHYDE** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>H)CHO. [131°]. One of the products got by reducing, by zinc-dust and alcohol, the mixture of chlorides got by acting on C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>Na)(CO<sub>2</sub>Ne) by PCl<sub>5</sub>. It is formed from C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>Cl)(COCl) present in the mixture. Salt.—BaA', 5aq.

**BROMO-SULPHO-BENZOIC ACID** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H)(CO<sub>2</sub>H) [2: 3 or 5: 1]. From the corresponding bromo-toluene sulphononic acid by chromic mixture (Retschy, A. 169, 45).—KHA'' 4aq.—BaA'' 2aq.—PbA'' 2aq.

**Bromo-sulpho-benzoic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H)(CO<sub>2</sub>H) [1:3:5]. From *m*-bromo-benzoic acid and SO<sub>3</sub> (Hübner a. Upmann, Z. [2] 6, 295; Roeters van Lennen, Z. [2] 7, 67; Böttinger, B. 7, 1779). Delicate deliquescent needles. Potash-fusion converts it into *s*-di-oxo-benzoic acid.

**Salts.**—NaHA''.—AgA''.—CaA'' 1½aq.—BaA'' 2½aq.—BaHA'' aq.—CuA''.

**Bromo-sulpho-benzoic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H)(CO<sub>2</sub>H) [4:2:1]. From bromo-toluene *o*-sulphononic acid by chromic mixture (Weiss, A. 169, 26).—KHA''—CaA''—BaA'': V. sol. water.

**Imide** C<sub>6</sub>H<sub>4</sub>Br<SO<sub>2</sub>>NH. **Bromo-benzoic sulphinide**. [217°]. From (4, 1, 2)-bromo-toluene sulphamide and KMnO<sub>4</sub>. Also from the acid K salt by successive treatment with PCl<sub>5</sub> and NH<sub>3</sub> (Remsen a. Bayley, Am. 8, 229). Long needles (from water); v. sol. alcohol and hot water, v. sl. sol. HCl aq. Sublimes at 200°. Its taste is extremely sweet at first and then extremely bitter.—Ba(C<sub>6</sub>H<sub>4</sub>BrNSO<sub>2</sub>)<sub>2</sub> 7½aq.—Ca(C<sub>6</sub>H<sub>4</sub>BrNSO<sub>2</sub>)<sub>2</sub> 7½aq.—AgC<sub>6</sub>H<sub>4</sub>BrNSO<sub>2</sub>—C<sub>6</sub>H<sub>4</sub>(C<sub>6</sub>H<sub>4</sub>BrNSO<sub>2</sub>)<sub>2</sub> [199°]; formed by successive treatment with PCl<sub>5</sub> and alcohol.

**Bromo-sulpho-benzoic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H)(CO<sub>2</sub>H) [4:3:1]. Formed by ox-

idation of the corresponding bromo-toluene sulphononic acid (Hasselbarth, A. 169, 12).—KHA'' aq.—BaA'' 4aq.—PbA'' 2aq.

**Bromo-sulpho-benzoic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H)(CO<sub>2</sub>H) [4: 2 or 3: 1]. Probably identical with the preceding. From *p*-bromo-benzoic acid and fuming H<sub>2</sub>SO<sub>4</sub> heated for 8 hours at 130° (Böttinger, A. 191, 18). Matted needles, v. sl. water.

**Salts.**—BaHA'' 2aq.—Ag<sub>2</sub>A'' 3aq.—BaA'' 8aq.—BaH<sub>2</sub>A'' 4½aq.—CuA'' 3aq.—PbA'' 7aq.

**Chloride** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>Cl)CO<sub>2</sub>H. [197°] (with decomposition). Needles (from ether). M. sol. cold ether, which separates it from another chloride.

**Acid ether** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>Et)(CO<sub>2</sub>H). [84°]. From the chloride and alcohol.

**Amic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>NH<sub>2</sub>)CO<sub>2</sub>H. [230°].—BaA', 12aq.

**Amic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>H)CONH<sub>2</sub>. [262°]. **Amic ether** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>2</sub>Et)(CONH<sub>2</sub>) [128°].

**Bromo-di-sulpho-benzoic acid** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H)<sub>2</sub>CO<sub>2</sub>H. From *p*-bromo-toluene disulphononic acid and boiling fuming HNO<sub>3</sub> (Kornatzki, A. 221, 196).—K<sub>3</sub>A''' aq.—Ba<sub>3</sub>A''' 12aq.

**Chloride**. [151°]. Trimetric tables from ether).

**Amide**. [above 260°]. Small prisms in stars.

**BROMO-SULPHO-PHENYL-PROPIONIC ACID** C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H). *i.e.*

[4:3:1] C<sub>6</sub>H<sub>4</sub>Br(SO<sub>3</sub>H).CH<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H. Prepared by the action of fuming sulphuric acid on *p*-bromo-phenyl-propionic acid (Göring, C. C. 1877, 793, 808). Non-deliquescent rhombic plates (containing 2½aq). *a:b:c* = 1:3013:1:07881.

**Salts.**—NaHA'' 3aq.—BaA'' 2aq.—H<sub>2</sub>BaA'' 8aq.; triclinic crystals: *a:b:c* = 0:4941:1:05046; *α* = 68° 36'; *β* = 98° 22'; *γ* = 83° 38'.—CaA'' 3aq.—CaH<sub>2</sub>A'' 8aq.; monoclinic crystals: *a:b:c* = 0:7062:1:09774; *β* = 86° 45'.

**DI-BROMO-SULPHO-PYROMUCIC ACID**

CB<sub>2</sub> = C—CO<sub>2</sub>H

| >O Di-bromo-sulpho-furfurane.  
CB<sub>2</sub> = C—SO<sub>3</sub>H

**carboxylic acid**. Formed by sulphonation of di-bromo-pyromucic acid [192°] with fuming H<sub>2</sub>SO<sub>4</sub>. By the action of bromine upon its barium salt, di-bromo-maleic acid is formed. By zinc-dust and aqueous NH<sub>3</sub> it is debrominated, yielding sulpho-pyromucic acid. A''Ba 5aq: easily soluble long fine needles (Hill a. Palmer, B. 18, 2096).

**BROMO-SULPHYDRO-BENZOIC ACID**

C<sub>6</sub>H<sub>4</sub>Br(SH)CO<sub>2</sub>H(?) [256°] (U.); [243°] (L.). From the chloride of sulphonated *m*-bromo-benzoic acid by tin and HCl (Upmann, Z. 1870, 295; Van Lennen, Z. 1871, 67). Needles, insol. water. Reduced by sodium-amalgam to C<sub>6</sub>H<sub>4</sub>(SH)CO<sub>2</sub>H. Iodine converts its Na salt into sn acid [130°].

**Salts.**—ZnA''<sub>2</sub>—PbA''<sub>2</sub>—BaA''<sub>2</sub>

**Bromo-sulphydro-benzoic acid**

C<sub>6</sub>H<sub>4</sub>Br(SH)CO<sub>2</sub>H. [194°]. From the chloride of (1, 3, 5)-bromo-sulpho-benzoic acid by tin and HCl (Frerichs, B. 7, 795). Laminæ.—PbA', 3aq.

**BROMO-TEREPHTHALIC ACID**

C<sub>6</sub>H<sub>4</sub>Br(CO<sub>2</sub>H)<sub>2</sub> [2:1:4]. [306° cor.]. Needles

containing aq (Fis.) or anhydrous (Fil.). Prepared by oxidation of bromo-toluic acid with  $\text{KMnO}_4$  (Fischli, *B.* 12, 619), by oxidation of bromo-cymene (Fileti, *G.* 16, 286), or of *p*-phenyl-toluene [129°] (Carnelley a. Thomson, *C. J.* 51, 88). It gives a sublimate anhydride [245°].

Salts.— $\text{K}_2\text{A}'$ : needles.— $\text{Ag}_2\text{A}$ : aq. White insoluble flocculent pp.— $\text{A}'\text{Cu}$ : light blue pp.

Chloride  $\text{C}_6\text{H}_3\text{Br}(\text{COCl})_2$ . [345° cor.).

Amide  $\text{C}_6\text{H}_3\text{Br}(\text{CONH}_2)_2$ . [270°]: insoluble needles.

Methyl ether  $\text{C}_6\text{H}_3\text{Br}(\text{CO.OEt})_2$ . [42°] (Fis.); [52°] (Fil.). (above 300°). Needles.

Di-bromo-terephthalic acid  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$ . [6:3:4:1]. Formed by oxidation of di-bromo-*p*-toluic acid [195°] with  $\text{KMnO}_4$  (Schultz, *B.* 18, 1762) or of di-bromo-cymene with dilute  $\text{HNO}_3$  (Claus a. Wimmel, *B.* 13, 902). Lamine (from  $\text{HOAc}$ ); does not melt below 320°.

Salts.— $\text{A}'\text{Ca}$ : easily soluble microscopic needles.— $\text{A}'\text{Ba}$  2aq and  $\text{A}'\text{Ba}$  5aq: microscopic needles.

Ethyl ether  $\text{A}'\text{Et}_2$ . [121°]. (c. 335°). Pearly plates.

*o*-Di-bromo-terephthalic acid.

Hexa-hydrate  $\text{C}_6\text{H}_2\text{Br}_2(\text{CO}_2\text{H})_2$ . [2:3:1:4].

Di-*o*-bromo-hexa-hydro-benzene-di-*p*-carboxylic acid. Formed by direct combination of tetra-hydro-terephthalic acid with Br in the cold. Granular crystals (containing aq). Nearly insol. cold water, sparingly in hot. By  $\text{Ag}_2\text{O}$  it is converted into an acid (probably  $\text{C}_6\text{H}_2(\text{OH})_2(\text{CO}_2\text{H})_2$ ) which by treatment with bromine yields tetra-bromo-pyrocatechin (Baeyer, *B.* 19, 1808).

DI-BROMO-TETRADECANF.  $\text{C}_{14}\text{H}_{10}\text{Br}_2$ . Tetradecylene bromide. [0°]. Colourless liquid. Formed by addition of Br to tetradecylene (Kraft, *B.* 17, 1372).

HEXA-BROMO-DITHIENYL  $\text{C}_6\text{Br}_6\text{S}_2$ . [255°].

uncor.]. Formed by heating an acetic acid solution of dithienyl with an excess of bromine (Nahsen, *B.* 17, 2198). Small needles. V. sol. hot benzene, v. sl. sol. cold benzene and hot alcohol.

TRI- $\omega$ -BROMO-DI-THIENYL-ETHANE

$\text{CBr}_2\text{CH}(\text{C}_6\text{H}_4\text{S})_2$ . [102°]. Obtained by adding  $\text{H}_2\text{SO}_4$  to a mixture of thiophene and bromal dissolved in acetic acid. Small pyramids. V. sol. ether,  $\text{CS}_2$ , and hot alcohol. With isatin and  $\text{H}_2\text{SO}_4$  it gives a violet-red colour (Peter, *A.* 17, 1344).

DI- $\omega$ -BROMO-DI-THIENYL-ETHYLENE

$\text{CBr}_2\text{C}(\text{C}_6\text{H}_4\text{S})_2$ . Formed by boiling tri-bromo-di thiényl-ethane with alcoholic KOH, or better KCN (Peter, *B.* 17, 1344). Colourless oil. Volatile with steam. Gives a violet-red colour with isatin and  $\text{H}_2\text{SO}_4$ .

BROMO-THIENYL METHYL KETONE

$\text{C}_6\text{SH}_2\text{Br.CO.CH}_3$ . Bromo-acetothienone. [91°]. Formed by the action of acetyl chloride upon mono- or di-bromo-thiophene in presence of  $\text{AlCl}_3$ . Stout colourless needles. Sol. hot alcohol, less in cold. Very volatile with steam. By alkaline  $\text{KMnO}_4$  it is oxidised to bromo-thiophene-carboxylic acid [140°].

Phenyl hydrazide

$\text{C}_6\text{SH}_2\text{Br.C}(\text{N.HPh})_2\text{CH}_3$ . [122°]; tables; sl. sol. alcohol (Gattermann a. Römer, *B.* 19, 689).

BROMO-THIO-CRESOL v. BROMO-TOLYL MERCAPTAN.

DI-BROMO-THIOHYDANTOIN  $\text{C}_6\text{H}_4\text{ON}_2\text{SBr}_2$ .

Formed by the action of bromine on a solution of thiohydantoin in aqueous HCl (Mulder, *B.* 8, 1263; Kramps, *B.* 13, 789). Colourless crystals. Insol. cold water, sol. alcohol and ether. Decomposed by hot water.

\*BROMO-THIO-OXY-BENZOIC ACID v. BROMO-SULPHYDRO-BENZOIC ACID.

(a) -BROMO-THIOPHENE  $\text{C}_6\text{SH}_3\text{Br}$ . 'B'.

Bromo-thiophene. (150°). S.G.  $\frac{23}{23}$  1.652. Colourless liquid. Formed by bromination of thiophene (Meyer, *B.* 16, 1472). Isolated from the crude di-bromo-thiophene obtained by fractional bromination of benzene that contains thiophene. By EtBr and Na it is converted into 'B'-ethyl-thiophene (Schleicher, *B.* 18, 3015).

Di-bromo-thiophene  $\text{C}_6\text{SH}_2\text{Br}_2$ . (211° cor.). S.G.  $\frac{23}{23}$  2.147. Colourless oil. Formed by dropping bromine into thiophene cooled with water. Prepared by fractional bromination of benzene that contains thiophene. With isatin and  $\text{H}_2\text{SO}_4$  it gives a deep-blue colour (Meyer, *B.* 16, 1469; Meyer a. Stadler, *B.* 18, 1488).

Tri-bromo-thiophene  $\text{C}_6\text{SHBr}_3$ . [29°]. (260° cor.). Formed by further bromination of di-bromothiophene. Long white glistening crystals. V. sol. hot alcohol and ether, sl. sol. cold alcohol. Gives the indophenine reaction. By sulphonation and debromination it yields thiophene-( $\beta$ )-sulphonic acid (Rosenberg, *B.* 18, 1773).

Tetra-bromo-thiophene  $\text{C}_6\text{SBr}_4$ . [112°]. (326° cor.). Long white needles. Formed by further bromination of di-bromo-thiophene (Meyer a. Kreis, *B.* 16, 2172).

BROMO-THIOPHENE-CARBOXYLIC ACID

$\text{C}_6\text{SH}_2\text{Br}(\text{CO}_2\text{H})$ . [140°]. Formed by oxidation of bromo-thienyl methyl ketone with alkaline  $\text{KMnO}_4$ . Colourless glistening needles (from water). Sublimes in pearly spikes. M. sol. hot water, nearly insol. cold water (Gattermann a. Römer, *B.* 19, 690).

Di-bromo-thiophene-(a)-carboxylic acid

$\text{C}_6\text{SHBr}_2\text{CO}_2\text{H}$ . Di-bromo-thiophenic acid. [222°]. Obtained by bromination of (a)-thiophene-carboxylic acid (q.v.). White monoclinic needles. Sublimes on heating. V. sol. alcohol and ether, sl. sol. hot water, insol. cold water. Sparingly volatile with steam. Isatin and  $\text{H}_2\text{SO}_4$  yield a dirty-green colouration quickly becoming brown. A solution of the ammonium salt gives white pps. with  $\text{AgNO}_3$ ,  $\text{Pb}(\text{OAc})_2$ ,  $\text{Hg}_2\text{NO}_3$ , and  $\text{SnCl}_2$ ; yellow pp. with  $\text{FeCl}_3$ ; and greenish-white pp. with  $\text{CuSO}_4$ .

Salts.— $\text{A}'\text{Ag}$ : white curly pp. becoming crystalline.— $\text{A}'\text{K}$ : easily soluble crystals.— $\text{A}'\text{Ba}$  3aq: white needles, v. sol. hot water, sl. sol. cold.

Chloride  $\text{C}_6\text{SHBr}_2\text{COCl}$ : (250°-270°); silky needles.

Amide  $\text{C}_6\text{SHBr}_2\text{CONH}_2$ : [167°]; fine white felted needles; v. sol. alcohol and ether, sparingly in hot water.

Methyl ether  $\text{C}_6\text{SHBr}_2\text{CO.Me}$ : [80°]; white needles (Peter, *B.* 18, 543; Bonz, *B.* 18, 2308).

DI-BROMO-THIOPHENE-SULPHONIC ACID

$\text{C}_6\text{HBr}_2\text{S.SO}_3\text{H}$ . Formed by sulphonating di-bromo-thiophene. By sodium-amalgam it is

reduced to thiophene-*'S'*-sulphonic acid.— $\text{PbA}'_2$ , 5 $\frac{1}{2}$ aq: small crystals, sol. hot water.

**Chloride**  $\text{C}_4\text{HBr}_2\text{S.SO}_2\text{Cl}$ : [33°].

**Amide**  $\text{C}_4\text{HBr}_2\text{S.SO}_2\text{NH}_2$ : [147°]; felted needles; sparingly soluble in water (Langer, *B.* 17, 1566; 18, 553; Rosenberg, *B.* 18, 3030).

**Di-bromo-thiophene-di-sulphonic acid**  $\text{C}_4\text{SBr}_2(\text{SO}_3\text{H})_2$ . Obtained by boiling the anhydride with alkalis. It very readily splits off  $\text{H}_2\text{O}$  with conversion into the anhydride.

**Salts**.— $\text{Na}_2\text{A}''$  3aq: very soluble silky needles.— $(\text{NH}_4)_2\text{A}''$  aq.— $\text{PbA}''$ : plates, sol. hot water.— $\text{BaA}''$  aq: sparingly soluble white glistening spikes.

**Anhydride**  $\text{C}_4\text{SBr}_2<\text{SO}_2>\text{O}$ : white glistening plates, v. sol. alcohol and benzene, insol. water and ligroin. Obtained by the action of fuming sulphuric acid (4 vols.) on di-bromo-thiophene (1 vol.).

**Chloride**  $\text{C}_4\text{SBr}_2(\text{SO}_2\text{Cl})_2$ : [220°]; glistening white needles; sol. ether.

**Amide**  $\text{C}_4\text{SBr}_2(\text{SO}_2\text{NH}_2)_2$ : [c. 270°]; crystalline powder; nearly insol. water (Langer, *B.* 17, 1569; 18, 554; Rosenberg, *B.* 18, 3030).

**Tri-bromo-thiophene-sulphonic acid**  $\text{C}_4\text{SBr}_3(\text{SO}_3\text{H})$ . Formed together with the anhydride by sulphonation of tri-bromo-thiophene [29°].— $\text{BaA}'_2$  aq: sparingly soluble white warty crystals.

**Anhydride**  $(\text{C}_4\text{SBr}_3\text{SO}_2)_2\text{O}$ : [116°]; volatile with steam; white solid; v. sol. alcohol and ether, v. sl. sol. water.

**Chloride**  $\text{C}_4\text{SBr}_3(\text{SO}_2\text{Cl})$ : [126°]; needles.

**Amide**  $\text{C}_4\text{SBr}_3(\text{SO}_2\text{NH}_2)$ : needles (from water) (Rosenberg, *B.* 18, 1774, 3028).

**DI-BROMO-THIOPHENE CARBOXYLIC ACID** v. DI-BROMO-THIOPHENE-CARBOXYLIC ACID.

**BROMO-THIO-PHENOL** v. BROMO-PHENYL MERCAPTAN.

**TETRA-BROMO-THIOPHTHENE**  $\text{C}_6\text{S}_2\text{Br}_4$ , i.e.  $\text{CBr:CBBr}$

$\begin{array}{c} \text{S} \\ | \\ \text{C} = \text{C} \\ | \\ \text{S} \end{array} \cdot \text{CBr:CBBr}$ . [172°]. Formed by bromination

of thiophthene. Long white needles (from benzene). V. sol. hot benzene, sl. sol. alcohol (Biedermann a. Jacobsen, *B.* 19, 2447).

**BROMO-THIOTOLUENE** v. BROMO-METHYL-THIOPHENE.

**BROMO-THIOXENE** v. BROMO-*TY*-METHYL-THIOPHENE.

**m-BROMO-THYMOHYDROQUINONE**

$\text{C}_9\text{HMePrBr}(\text{OH})_2$  [1:4:5:3:6]. [53°]. Formed by the action of conc.  $\text{HBr}$  upon thymoquinone at a low temperature. Colourless needles (Schniter, *B.* 20, 1318). Formed also by reduction of the corresponding quinone with  $\text{SO}_2$  (Mazzara a. Discalzo, *G.* 16, 195). Changes spontaneously to a substance melting at 37° (M. a. D.).

**Di-acetyl derivative**  $\text{C}_9\text{HMePrBr}(\text{OAc})_2$ , [91°]. From thymoquinone and  $\text{AcBr}$  (Schulz, *B.* 15, 657).

**Di-bromo-thymo-hydroquinone**

**Di-acetyl derivative**  $\text{C}_9\text{MePrBr}_2(\text{OAc})_2$ , [122°]. From di-acetyl bromo-thymo-hydroquinone and  $\text{Br}$  (S.).

**BROMO-THYMOLS** and their ethyl derivatives appear to have been obtained by Paterno a. Canzoneri, *G.* 10, 233, Armstrong a. Thorpe,

*Brit. Assoc. Report*, 1875, 112; and Lallemand, *A. Ch.* [3] 49, 148.

**BROMO-THYMOL SULPHONIC ACID**

$\text{C}_{10}\text{H}_7\text{BrSO}_3$ , i.e.  $\text{C}_9\text{HMePrBr}(\text{OH})(\text{SO}_3\text{H})$ . From potassium thymol (*a*)-sulphonic acid and  $\text{Br}$ .— $\text{KA}'_2$  13aq.— $\text{BaA}'_2$  (Engelhardt a. Latschinoff, *Z.* 1871, 261).

**m-BROMO-THYMOQUINONE**  $\text{C}_9\text{HMePrBrO}$ , [1:4:5:3:6]. [8°] (M. a. D.); [45°] (S.). Formed by oxidation of the corresponding bromo-thymo-hydroquinone with  $\text{Fe}_2\text{Cl}_6$ . Glistening yellow plates (Schniter, *B.* 20, 1318). From bromo-amido-thymol and nitrous acid (Mazzara a. Discalzo, *G.* 16, 195). A crystalline bromo-thymoquinone was got by Corstjen (*J. pr.* [2] 3, 55) in brominating thymoquinone. Andresen (*J. pr.* [2] 23, 184) obtained a liquid isomeric by brominating thymoquinone chloro-imide.

**Di-bromo-thymo-quinone**  $\text{C}_9\text{Br}_2\text{MePrO}_2$ , [74°]. The ethereal extract from the product of the action of  $\text{HBr}$  on thymo-quinone-chloro-imide (*q. v.*) is evaporated and the residue distilled with steam (Andresen, *J. pr.* [2] 23, 184). From thymoquinone and  $\text{Br}$  (C.). Lemon-yellow plates (by adding water to the alcoholic solution).

**o-BROMO-TOLUENE**  $\text{C}_6\text{H}_5\text{Br}$  i.e.  $\text{C}_6\text{H}_4\text{MeBr}$  [1:2]. (182°). S.G.  $^{25}$  1.2031. S.V. 141-95 (Schiff, *B.* 19, 564).

**Formation**.—1. Together with *p*-bromo-toluene, by brominating cold toluene, in the dark, in daylight, or with addition of iodine (Hübner a. Wallach, *Z.* [2] 5, 22, 138, 499; *A.* 154, 293; Dmochowsky, *B.* 5, 333; Kekulé, *A.* 137, 192; Beilstein, *A.* 143, 369; Cannizzaro, *A.* 141, 198; Glinzer a. Fittig, *A.* 133, 47; 136, 301; Fittig, *A.* 142, 39; Rosenstiehl a. Nikitoroff, *Z.* [2] 5, 635; Hübner a. Retschy, *Z.* [2] 7, 618; Lauth a. Grimaux, *B.* 1866, i, 347; 1867, i, 108; Körner, *G.* 4; Hübner a. Jannasch, *A.* 170, 117; Louguinine, *B.* 4, 514; Reynan, *B.* [2] 26, 533; Schramm, *B.* 18, 607).—2. From *o*-toluidine by the diazo-reaction (Wroblewsky, *A.* 168, 171; Jackson, *Am.* 1, 93).—3. Together with naphthalene, by the action of (*a*)-bromo-naphthalene on toluene in presence of  $\text{Al}_2\text{Cl}_6$  (Roux, *B.* [2] 45, 520).

**Properties**.—Oil.

**Reactions**.—1. Converted by dilute  $\text{HNO}_3$  into *o*-bromo-benzoic acid (Zincke, *B.* 7, 1502).—2. *Sodium* has no action at 15°.—3. *Sodium* and  $\text{MeI}$  form *o*-xylene.—4. The *copper-zinc* couple has no action (Gladstone a. Tribe, *C. J.* 47, 448).

**m-Bromo-toluene**  $\text{C}_6\text{H}_4\text{MeBr}$  [1:3]. (184°). S.G.  $^{25}$  1.401 (W.).

**Formation**.—1. From  $\text{C}_6\text{H}_5\text{MeBr}(\text{NH}_2)$  [1:3:4] by the diazo-reaction (Wroblewsky, *Z.* [2] 7, 609; *A.* 168, 155; Grete, *A.* 177, 231).—2. From the same bromo-*p*-toluidine by successive conversion into  $\text{C}_6\text{H}_4(\text{NO}_2)\text{MeBr}(\text{NH}_2)$  [5:1:3:4],  $\text{C}_6\text{H}_4(\text{NO}_2)\text{MeBr}$  [5:1:3],  $\text{C}_6\text{H}_4(\text{NH}_2)\text{Me}$  [5:1], and  $\text{C}_6\text{H}_5\text{MeBr}$  [5:1] (Wroblewsky, *A.* 192, 206).

**Properties**.—Liquid, even at  $-20^\circ$ . Oxidised by chromic mixture to *m*-bromo-benzoic acid.

**p-Bromo-toluene**  $\text{C}_6\text{H}_4\text{MeBr}$  [1:4]. [285°]. (185° i. v.) (Hübner a. Post, *A.* 169, 6). S.G.  $^{25}$  1.411 (Kekulé, *A.* 137, 192).

**Formation**.—Together with *o*-bromo-toluene (*q. v.*) by brominating toluene.

**Properties**.—Trimetric crystals.

**Reactions.**—1.  $\text{CrO}_3$  forms *p*-bromo-benzoic acid.—2. Sodium even at  $15^\circ$  forms ditolyl (Zincke, *B.* 4, 396; Louguine, *B.* 4, 514).—3. Sodium and  $\text{MeI}$  gives *p*-xylene.—4. The copper-zinc couple has no action (G. a. T.).—5. Taken internally, it is excreted as *p*-bromobenzoic and *p*-bromo-hippuric acids (Preusse, *H.* 5, 63).—6.  $\text{CrO}_3$  forms  $\text{C}_6\text{H}_4\text{BrCH}(\text{O.CrOCl})_2$  (Etard, *A. Ch.* [5] 22, 241).

*o*-Bromo-toluene v. BENZYL BROMIDE.

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [1:2:3]. [28°]. From  $\text{C}_6\text{H}_5(\text{CH}_3)(\text{NH}_2)\text{Br}_2$  [86°] by displacing  $\text{NH}_2$  by  $\text{H}$  (Neville a. Winther, *C. J.* 37, 431). Gives on oxidation with  $\text{HNO}_3$  di-bromo-benzoic acid [146°–148°]. On nitration it gives a mono-nitro-derivative [57°] which reduces to an amido-compound [53°].

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [1:2:4]. From di-bromo-*m*-toluidine [75°] by eliminating  $\text{NH}_2$ . Also from  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NH}_2)\text{Br}$  [1:2:4] by diazo-perbromide reaction. Oil. On nitration gives di-bromo-nitro-toluene [80°]. On oxidation with  $\text{HNO}_3$  gives di-bromo-benzoic acid [169°].

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [1:2:5]. (236°). S.G.  $d_4^{20}$  1.813. Formed by brominating toluene (Wroblewski, *Z.* [2] 6, 239). From acetyl-*o*-toluidine by brominating, saponifying, and displacing  $\text{NH}_2$  by  $\text{Br}$  by the diazo-reaction (N. a. W.). Also from acetyl-*m*-toluidine in the same way. Thus  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NH}_2)\text{Br}$  [1:2:5] and  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Br}(\text{NH}_2)$  [1:2:5] give the same  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Br}_2$ . Oil. On nitration it gives a nitro-compound [88°], which reduces to an amido-compound [85°]. Oxidised by dilute  $\text{HNO}_3$  it gives di-bromo-benzoic acid [149°–153°]; this distilled with lime gives a solid, [86°], probably *p*-di-bromo-benzoic.

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [1:2:6]. (216°). S.G.  $d_4^{20}$  1.812. From di-bromo-*m*-toluidine [35°] (Wr.; N. a. W.) or from di-bromo-*p*-toluidine [88°] by diazo-reaction. Oil. On nitration it gives two nitro-compounds, [161°], and [c. 80°]. On oxidation it gives di-bromo-benzoic acid [150°–167°].

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [1:3:4]. (211°). S.G.  $d_4^{20}$  1.812. Formed in brominating toluene containing iodine in sunlight (Jannasch, *A.* 176, 286). Also from bromo-*p*-toluidine by the diazo-perbromide reaction (N. a. W.; Wr.). Oil. Gives a nitro-derivative, [87°], reducing to an amido-derivative [98°]. By oxidation with  $\text{CrO}_3$  it gives di-bromo-benzoic acid [233°].

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [1:3:5]. [39°]. (246°). From  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NH}_2)\text{Br}_2$  [73°] and its isomeride [46°] (N. a. W.; Wr.). With  $\text{HNO}_3$  it gives two di-nitro-compounds, [158°] and [105°]. On oxidation with  $\text{CrO}_3$  it gives di-bromo-benzoic acid [208°–210°].

**Di-bromo-toluene**  $\text{C}_6\text{H}_3\text{MeBr}_2$  [108°]. The existence of this body, said to be formed in brominating toluene (Fittig, *A.* 147, 39), is called in question by Neville and Winther.

Other Di-bromo-toluenes are described as BENZYLIDENE BROMIDE and BROMO-BENZYL BROMIDE.

**Tri-bromo-toluene**  $\text{C}_6\text{H}_2\text{MeBr}_3$  [1:2:3:4]. [44°]. From  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NH}_2)\text{Br}_2$ , [97°], by nitrous gas (Neville a. Winther, *C. J.* 37, 447). On nitration it gives a nitro-compound [107°].

**Tri-bromo-toluene**  $\text{C}_6\text{H}_2\text{MeBr}_3$  [1:2:3:5]. [53°]. From di-bromo-*o*-toluidine [46°] by diazo-

perbromide reaction (N. a. W.). Long flat needles.

**Tri-bromo-toluene**  $\text{C}_6\text{H}_2\text{MeBr}_3$  [1:2:5:6]. [59°]. From [1:3:2:5:6]  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NH}_2)\text{Br}_2$  [94°] by nitrous gas. On nitration it gives a nitro-compound [91°].

**Tri-bromo-toluene**  $\text{C}_6\text{H}_2\text{MeBr}_3$  [1:2:4:6]. [66°]. (290°). From tri-bromo-*m*-toluidine [104°] by nitrous gas (N. a. W.; Wroblewski, *A.* 168, 194). On nitration it gives a di-nitro-compound [c. 220°].

**Tri-bromo-toluene**  $\text{C}_6\text{H}_2\text{MeBr}_3$  [1:3:4:5]. [89°]. From di-bromo-*p*-toluidine by diazo-perbromide reaction (N. a. W.).

**Tri-bromo-toluene**  $\text{C}_6\text{H}_2\text{MeBr}_3$  [1:3:4:6]. [112°]. From di-bromo-*m*-toluidine [75°] and from di-bromo-toluidine [85°] by diazo-perbromide reaction (N. a. W.).

**Tri-bromo-toluene** ? [150°]. Formed by heating potassium tri-bromo-phenol with KOAc (Pfaukueh, *J. pr.* [2] 6, 103).

**Tetra-bromo-toluene**  $\text{C}_6\text{HMeBr}_4$  [1:2:3:4:6]. [105°–108°]. From tetra-bromo-*m*-toluidine [221°] by alcohol and nitrous gas. Also from tri-bromo-*m*-toluidine [100°] by diazo-perbromide reaction (Neville a. Winther, *C. J.* 37, 449). Fuming  $\text{HNO}_3$  forms the nitro-compound [216°].

**Tetra-bromo-toluene**  $\text{C}_6\text{HMeBr}_4$  [1:3:4:5:6]. [111°]. From tri-bromo-*m*-toluidine [96°], by diazo-perbromide reaction (N. a. W.). Its nitro-compound melts at [212°].

**Tetra-bromo-toluene**  $\text{C}_6\text{HMeBr}_4$  [1:2:3:5:6]. [117°]. From tri-bromo-*m*-toluidine [94°] by diazo-perbromide reaction. Its nitro-derivative melts at [213°].

**Penta-bromo-toluene**  $\text{C}_6\text{MeBr}_5$  [285°]. From tetra-bromo-*m*-toluidine by diazo-perbromide reaction (Neville a. Winther, *C. J.* 37, 450). From toluene  $\text{Al}_2\text{Br}_6$  and  $\text{Br}$  at  $0^\circ$  (Gustavson, *B.* [2] 28, 317; *B.* 10, 971). Long needles (from benzene).

#### ***o*-BROMO-TOLUENE SULPHONIC ACID**

$\text{C}_6\text{H}_4\text{BrSO}_3$  i.e.  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_3\text{H})$  [1:2:5?]. From *o*-bromo-toluene by sulphonation (Hübner a. Post, *A.* 169, 31; cf. Dimochowsky, *B.* 5, 333). Also from brominated (1, 4, 3)-*p*-toluidine sulphonic acid by displacement of  $\text{NH}_2$  by  $\text{H}$  (Pechmann, *A.* 173, 212). Reduced by sodium-amalgam to toluene-*m*-sulphonic acid.

**Salts.**— $\text{KA}'\text{aq.}$ — $\text{NaA}'\text{aq.}$ — $\text{BaA}'_2\text{aq.}$ — $\text{BaA}'_2\text{aq.}$  S. (of  $\text{BaA}'_2$ ) 25 at  $14^\circ$ .— $\text{PbA}'_2\text{aq.}$  S. (of  $\text{PbA}'_2$ ) 52 at  $18^\circ$ .— $\text{PbA}'_2\text{aq.}$

**Chloride**  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{Cl})$ . [53°].

**Amide**  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{NH}_2)$ . [134°].

#### ***o*-Bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_3\text{H})$  [1:2:5?]. From *o*-toluidine by sulphonating and displacing  $\text{NH}_2$  by  $\text{Br}$  (Pagel, *A.* 176, 294; Neville a. Winther, *B.* 13, 1943; cf. Gerver, *A.* 163, 384). Reduced by sodium-amalgam to toluene-*m*-sulphonic acid.

**Salts.**— $\text{KA}'\text{aq.}$ — $\text{CuA}'_2\text{aq.}$ — $\text{BaA}'_2\text{aq.}$  S. 1:2 at  $25^\circ$  (P.).— $\text{BaA}'_2\text{aq.}$ — $\text{BaA}'_2\text{aq.}$  S. 8:9 at  $17.5^\circ$  (G.).— $\text{PbA}'_2\text{aq.}$ — $\text{CuA}'_2\text{aq.}$

**Chloride** [53°] (P.); [56°] (N. a. W.).

**Amide** [c. 135°] (P.); [147°] (N. a. W.).

This acid is probably identical with the preceding-  
***o*-Bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_3\text{H})$  [1:2:4]. From *o*-toluidine *p*-sulphonic acid by the diazo-reaction (Hayduck,

**A. 172, 206.**— $\text{KA}'$ : nodules of minute needles.— $\text{BaA}'$ , 2aq.— $\text{PbA}'$ , 2aq.

*Chloride*  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{Cl})$ . [54°].

*Amide*  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{NH}_2)$ . [151°].

**Bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_4\text{MeBrSO}_3\text{H}$  [1:3:5]. From bromo-*o*-toluidine sulphonic acid or from bromo-*p*-toluidine sulphonic acid by displacement of  $\text{NH}_2$  by H. Potash-fusion gives creosin (Neville a. Winther, *B.* 13, 1911; *C. J.* 41, 420).

*Chloride*  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{Cl})$ . [52°].

*Amide*  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{NH}_2)$ . [139°].

***m*-Bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_3\text{H})$ . Formed by sulphonating *m*-bromo-toluene (Grete, *B.* 7, 795; 8, 565; *A.* 177, 233).— $\text{BpA}'$ , aq.— $\text{SrA}'$ , aq.— $\text{CaA}'$ , 2aq.— $\text{MgA}'$ , 6aq.— $\text{CuA}'$ , 4aq.— $\text{PbA}'$ , 3aq. According to Wroblewsky (*A.* 168, 166; *Z.* [2] 7, 6) three bromo-toluene sulphonic acids are formed by sulphonating *m*-bromo-toluene, the Ba salts being  $\text{BaA}'$ , aq. S. 528,  $\text{BaA}'$ , 3aq. S. 1452, and  $\text{BaA}'$ , 2½aq. S. 5248 at 19°; Grete, however, could only obtain the acid just described.

**Bromo-toluene *o*-sulphonic acid**

$\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_3\text{H})$ . From (1, 4, 2)-toluidine sulphonic acid by bromination and elimination of  $\text{NH}_2$  (Weckwarth, *A.* 172, 196).— $\text{NaA}'$ , 1aq.— $\text{KA}'$ , aq.— $\text{BaA}'$ , 2½aq.— $\text{SrA}'$ , 2½aq.— $\text{PbA}'$ , 3½aq.— $\text{CuA}'$ , 3aq.

*Chloride*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{Cl})$ : crystalline at -20°.

*Amide*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{NH}_2)$ : [c. 164°]; needles.

**Bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_3\text{H})$ . From toluene by sulphonation, nitration, reduction, and displacement of  $\text{NH}_2$  by Br (Weckwarth, *A.* 172, 193; Hayduck, *A.* 177, 57).— $\text{BaA}'$ , aq.

*Chloride*. Oil, slowly solidifying.

*Amide*. Does not melt below 230°.

***p*-Bromo-toluene *m*-sulphonic acid**

$\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_3\text{H})$  [1:4:3]. [c. 108°]. From *p*-toluidine *m*-sulphonic acid by exchange of  $\text{NH}_2$  for Br. Formed also in sulphonating *p*-bromo-toluene (E. Richter, *A.* 230, 319; Post a. Retschy, *A.* 169, 7; v. Pechmann, *A.* 173, 208; Neville a. Winther, *C. J.* 37, 631). Lamine (containing aq).— $\text{BaA}'$ , 7aq.— $\text{SrA}'$ , 7aq.— $\text{PbA}'$ , 3aq.

*Chloride*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{Cl})$ . [61°].

*Amide*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{NH}_2)$ . [152°].

***p*-Bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_3\text{H})$  [1:1:2]. The chief product of the sulphonation of *p*-bromo-toluene (Hübner, *A.* 169, 6; *Z.* [2] 7, 618). Formed also from *p*-toluidine *o*-sulphonic acid by exchange of  $\text{NH}_2$  for Br (Jenssen, *A.* 172, 237). Reduced by sodium-amalgam to toluene *o*-sulphonic acid.— $\text{NaA}'$ , aq.— $\text{CaA}'$ , 4aq.— $\text{BaA}'$ , 1aq. S. 53 at 8°.— $\text{SrA}'$ , aq.— $\text{PbA}'$ , 3aq.— $\text{CuA}'$ , 7aq.

*Chloride*  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{Cl})$ . [35°].

*Amide*  $\text{C}_6\text{H}_4\text{MeBr}(\text{SO}_2\text{NH}_2)$ . [167°].

***p*-Bromo-toluene *ox*-sulphonic acid**

$\text{C}_6\text{H}_3\text{Br}(\text{CH}_2\text{SO}_3\text{H})$  [1:4]. ***p*-Bromo-benzyl sulphonic acid**. From *p*-bromo-benzyl bromide and  $\text{K}_2\text{SO}_3$  (Jackson a. Hartshorn, *Am.* 5, 264). Also from  $\text{C}_6\text{H}_4(\text{NH}_2)\text{CH}_2\text{SO}_3\text{H}$  by diazo-reaction (Mohr, *A.* 221, 222).— $\text{KA}'$ . S. 62 at 18°.— $\text{CaA}'$ , aq.— $\text{BaA}'$ , 1½aq.— $\text{BaA}'$ , aq. S. (of  $\text{BaA}'$ ) 67 at 18°.— $\text{PbA}'$ , aq. S. 2 at 18°.

*Chloride*. [107°] (M.); [115°] (J. a. H.).

**Bromo-toluene disulphonic acid**

$\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_3\text{H})_2$  [1:2:3:5]. From  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)(\text{SO}_3\text{H})$  by diazo-reaction (Limp-richt, *B.* 18, 2177; Hasse, *A.* 230, 294).— $\text{KA}'$ , 4aq.— $\text{BaA}'$ , 1½aq.

*Chloride* [90°].

*Amide* [238°].

***p*-Bromo-toluene disulphonic acid**

$\text{C}_6\text{H}_3\text{BrMe}(\text{SO}_3\text{H})_2$ . From *p*-bromo-toluene,  $\text{H}_2\text{SO}_4$  and  $\text{SO}_3$  (Kornatzki, *A.* 221, 192). Cauliflower-like deliquescent crystals. Boiled for sixteen hours with conc. nitric acid it forms sulphuric acid  $\text{C}_6\text{H}_3\text{Br}(\text{CO}_2\text{H})(\text{SO}_3\text{H})_2$  with  $\text{C}_6\text{H}_4(\text{NO}_2)\text{Br}(\text{MeSO}_3\text{H})$  and  $\text{C}_6\text{H}_3(\text{NO}_2)\text{Me}(\text{SO}_3\text{H})_2$ . Salts.— $\text{KA}'$ , aq.— $\text{BaA}'$ , 5aq.— $\text{PbA}'$ , 2aq.

*Chloride*. [99°]. Trimetric plates (from ether).

*Amide*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{NH}_2)_2$ . [above 260°].

**Bromo-toluene disulphonic acid**

$\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_3\text{H})_2$  [1:4:3:2]. Prepared from  $\text{C}_6\text{H}_4\text{Me}(\text{NH}_2)(\text{SO}_3\text{H})_2$  by diazo-reaction (Limp-richt, *B.* 18, 2179; E. Richter, *A.* 230, 324).— $\text{BaA}'$ , 6aq.— $\text{KA}'$ , aq.

*Chloride*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{Cl})_2$ . [129°-133°].

*Amide*  $\text{C}_6\text{H}_3\text{MeBr}(\text{SO}_2\text{NH}_2)_2$ . [above 240°].

**Di-bromo-toluene sulphonic acid**

$\text{C}_6\text{H}_2\text{MeBr}_2(\text{SO}_3\text{H})$ . From *o*-bromo-toluene *m*-sulphonic acid by nitration, and displacement of  $\text{NO}_2$  by Br (Schäfer, *A.* 174, 365).— $\text{NaA}'$ , 2aq.— $\text{BaA}'$ , 2½aq.

**Tri-bromo-toluene sulphonic acid**

$\text{C}_6\text{HMeBr}_3(\text{SO}_3\text{H})$ . From *o*-toluidine *p*-sulphonic acid by bromination and exchange of  $\text{NH}_2$  for Br (Hayduck, *A.* 174, 351).— $\text{KA}'$ .— $\text{BaA}'$ , 1½aq. The *chloride* is a syrup, the *amide* an amorphous powder.

**BROMO-(*o*)-TOLUIC ACID v. BROMO-PHENYL-ACETIC ACID.**

***p*-Bromo-*o*-toluic acid**  $\text{C}_6\text{H}_3\text{MeBr}(\text{CO}_2\text{H})$  [1:4:2]. [118° uncor.]. Fine white needles. Formed by oxidation of bromo-*o*-ethyl-toluene with dilute  $\text{HNO}_3$  (1:1) at 200° (Claus a. Piesczek, *B.* 19, 3088).

**Bromo-toluic acid**  $\text{C}_6\text{H}_4\text{MeBr}(\text{CO}_2\text{H})$  [1:3or4:2]. [167°]. From *o*-toluic acid and bromine in the cold (Jacobsen a. Wiers, *B.* 16, 1959; Racine, *A.* 239, 74). Needles; volatile with steam. On oxidation it gives bromo-phthalic acid [157°]. Salt.— $\text{BaA}'$ , 5aq.

*Methyl ether*  $\text{MeA}'$ . [46°].

**Bromo-*o*-toluic acid**  $\text{C}_6\text{H}_3\text{MeBrCO}_2\text{H}$

[1:4or5:2]. [176°]. Glistening needles. V. sl. sol. hot water. Formed by oxidation of bromo-*o*-xylene with dilute  $\text{HNO}_3$ .— $\text{CaA}'$ , 2aq (Jacobsen, *B.* 17, 2375). This acid is perhaps identical with the following.

**Bromo-*o*-toluic acid**  $\text{C}_6\text{H}_3\text{MeBr}(\text{CO}_2\text{H})$  [1:5:2]. [187°]. Formed by saponification of the nitrile. Sublimes in needles. V. sol. alcohol, v. sl. sol. water. By alkaline  $\text{KMnO}_4$  it is oxidised to bromo-phthalic acid [168°] (Nourrisson, *B.* 20, 1016).

*Amide*  $\text{C}_6\text{H}_3\text{MeBr}(\text{CONH}_2)$ . [182°]; pearly plates (from alcohol); sublimes in needles.

**Nitrile**  $\text{C}_6\text{H}_3\text{MeBr}(\text{CN})$  [1:5:2]. [70°]. Formed from bromo-*o*-toluidine by diazotisation and treatment with cuprous cyanide. Long needles. Easily volatile with steam.

**Bromo-*m*-toluic acid**  $\text{C}_6\text{H}_3\text{MeBr}(\text{CO}_2\text{H})$  [1:4:3]. [153°].

**Formation.**—1. From bromo-isocymene,  $C_6H_5MePrBr$  [1:3:4] by treatment with dilute  $HNO_3$  (Kelbe a. Czarnomski, A. 235, 296).—2. Together with the following acid, by brominating *m*-toluic acid in the cold (Jacobsen, B. 14, 2951).—3. From bromo-nitro-toluene [45°] by treatment with KCN and alcohol at 220°, and saponification of the resulting nitrile (Richter, B. 5, 425).

**Properties.**—Slender needles; sl. sol. cold HOAc. Oxidation gives (4, 1, 5)-bromo-isophthalic acid.

**Bromo-*m*-toluic acid**  $C_6H_3MeBrCO_2H$  [1:6:3]. [209° cor.].

**Formation.**—1. By oxidation of bromo-*m*-xylene (Fittig, A. 147, 32; Jacobsen, B. 14, 2952).—2. Together with the preceding by brominating *m*-toluic acid (J.).—3. By oxidising the corresponding bromo-*m*-isocymene (Kelbe, B. 15, 41).—4. From the corresponding amido-toluic acid by exchange of  $NH_2$  for Br (Remsen a. Kuhara, Am. 3, 431).

**Properties.**—Crystalline powder, sol. hot alcohol, insol. water.  $\rightarrow CaA'$ , 3aq.  $\rightarrow BaA'$ , 4aq.  $\rightarrow AgA'$ .

**Ethyl ether EtA'** [c. -5°]; (270°-275°). **Bromo-*p*-toluic acid**  $C_6H_3MeBr(CO_2H)$  [1:2:4]. [204°].

**Formation.**—1. By the oxidation of bromo-cymene  $C_6H_5MePrBr$  [1:4:2] (Landolph, B. 5, 268), bromo-*p*-xylene (Jannasch a. Dieckmann, A. 171, 83), bromo-*p*-ethyl-toluene (Remsen a. Morse, Am. 1, 138).—2. By brominating *p*-toluic acid in the cold (Brückner, B. 9, 407).

**Properties.**—Thin needles or laminae (from water); m. sol. hot water.

**Salts.**  $\rightarrow BaA'$ , 4aq.  $\rightarrow CaA'$ , 3!aq.  $\rightarrow CaA'$ , 3aq. **Bromo-*p*-toluic acid**  $C_6H_3MeBr(CO_2H)$  [1:3:4]. [196°]. Formed by oxidising bromo-*p*-cymene  $C_6H_5MePrBr$  [1:4:3] (Kelbe a. Koschnitzky, B. 19, 1731).

**Di-bromo-*m*-toluic acid**  $C_6H_2MeBr_2(CO_2H)$ . [186°]. Formed by oxidising crude di-bromo-xylene with  $CrO_3$  (Fittig, Ahrens, a. Mattheides, A. 147, 36). Minute needles (from alcohol).  $\rightarrow BaA'$ , 9aq.  $\rightarrow AgA'$ .

**Di-bromo-*p*-toluic acid**  $C_6H_2MeBr_2CO_2H$  [4:6:3:1]. [195°]. Needles (from alcohol). V. sl. sol. hot water. Formed by oxidation of di-bromo-*p*-xylene  $C_6H_2(CH_3)_2Br_2$  [1:4:3:6] in acetic acid solution with  $CrO_3$ . By further oxidation with  $KMnO_4$  it gives di-bromo-terephthalic acid  $C_6H_2Br_2(CO_2H)_2$  [6:3:4:1].

**Salts.**  $\rightarrow CaA'$ , 4aq. S. 1 at 20°.  $\rightarrow BaA'$ , 2aq. **Ethyl ether EtA'**: [49°]; (c. 310°); low g. needles (Schultz, B. 18, 1762).

**BROMO-*o*-TOLUIDINE**  $C_6H_4Me(NH_2)Br$  [1:2:3]. Formed by reducing bromo-nitro-toluene, itself got by the diazo-reaction from bromo-nitro-toluidine [88°]. Oil. Gives with bromine-water di-bromo-*o*-toluidine,  $C_6H_2(CH_3)(NH_2)Br_2$ , [47°]. Heated with conc.  $HCl$  at 160° it forms the above di-bromo-toluidine and a crystalline bromo-toluidine [55°] (Neville a. Winther, C. J. 87, 630).

**Bromo-*o*-toluidine**  $C_6H_4Me(NH_2)Br$  [1:2:4]. [32°]. (c. 255°). Formed by reducing the corresponding bromo-nitro-toluene, [45°] (Hübner a. Wallach, A. 154, 298; Körner, Z. 1869, 636; Hübner a. Roos, B. 6, 799; Wroblewsky, A. 168, 177; Heynemann, Z. [2] 6, 402; A. 168, 340;

Neville a. Winther, C. J. 87, 442). Laminae.  $\rightarrow B'HCl$ : six-sided trimetric tables, S. 827 at 11-5°.  $\rightarrow B'H_2SO_4$ .

**Bromo-*o*-toluidine**  $C_6H_4Me(NH_2)Br$  [1:2:5]. [58°]. Formed by brominating acetyl-*o*-toluidine (Wroblewsky, A. 168, 162; Z. [2] 7, 135). Also from bromo-nitro-toluene [55°] by tin and  $HCl$  (Grete, B. 8, 565; A. 177, 249). Rhombohedra (from alcohol). Its constitution is known because it gives the same di-bromo-toluene (q. v.) as bromo-*m*-toluidine. By displacement of  $NH_2$  by  $H$  it yields *m*-bromo-toluene.  $\rightarrow B'H_2SO_4$ .  $\rightarrow B'H_2SO_4$ , 1!aq.  $\rightarrow B'HCl$   $\rightarrow B'HNO_3$ : [183°]; S. 4-92 at 17°.

**Acetyl derivative**  $C_6H_4Me(NHAc)Br$ . [157°].

**Bromo-toluidine**  $C_6H_4Me(NH_2)Br$  [1:3:4]. [32°] (N. a. W.); [67°] (Wr.); [75°] (H. a. R.). By reducing the corresponding bromo-nitro-toluene (q. v.) (Neville a. Winther, C. J. 37, 442; Wroblewsky, A. 168, 177; Hübner a. Roos, B. 6, 800).

**Acetyl derivative**  $C_6H_4Me(NHAc)Br$ . [114°] (N. a. W.).

**Bromo-toluidine**  $C_6H_4Me(NH_2)Br$  [1:3:5]. [36°]. (c. 258°). S.G. 1.1412. Formed by reducing bromo-nitro-toluene, [81°]. Crystallises with difficulty (N. a. W.; Wroblewsky, A. 192, 203). Reduced by sodium-amalgam to *m*-toluidine.  $\rightarrow B'HCl$ .  $\rightarrow B'HNO_3$ . S. 2-6 at 13°.  $\rightarrow B'H_2SO_4$ .

**Acetyl derivative**  $C_6H_4Me(NHAc)Br$ . [168°].

**Bromo-*m*-toluidine**  $C_6H_4Me(NH_2)Br$  [1:3:6]. [78°]. (240°). Formed by brominating acetyl-*m*-toluidine and boiling the product with alcoholic potash (N. a. W.). Formed also by reducing (1,2,5)- $C_6H_3(CH_3)Br(NO_2)$ . It gives the same di-bromo-toluene (q. v.) as bromo-*o*-toluidine.  $\rightarrow B'HNO_3$ : prisms.

**Bromo-toluidine**  $C_6H_4Me(NH_2)Br$ . From *o*-bromo-toluene by nitration and reduction (Hübner a. Roos, B. 6, 801). Oil.  $\rightarrow B'HCl$ : S. 3-1 at 16°.  $\rightarrow B'HNO_3$ : 1-25 at 19°. Perhaps identical with the preceding.

**Bromo-*p*-toluidine**  $C_6H_4Me(NH_2)Br$  [1:4:3]. [26°] (Claus a. Steinberg, B. 16, 914). (240°). S.G. 1.150. From acetyl-*p*-toluidine by bromination and saponification (Wroblewsky, A. 168, 153). Elimination of  $NH_2$  gives *m*-bromo-toluene.  $\rightarrow B'HNO_3$ : [182°]; S. 2-533 at 19°.  $\rightarrow B'H_2SO_4$ , 1aq.  $\rightarrow B'H_2CO_3$ .

**Acetyl derivative**  $C_6H_4Me(NHAc)Br$ . [117-5°].

**Bromo-*p*-toluidine**  $C_6H_4Me(NH_2)Br$  [1:4:2]. [26°]. Formed by reducing the corresponding bromo-nitro-toluene (Neville a. Winther, C. J. 39, 85).  $\rightarrow B'HBr$ .  $\rightarrow B'HCl$  (Wallach, A. 235, 255).

**Di-bromo-*o*-toluidine**  $C_6H_2(CH_3)(NH_2)Br_2$  [1:2or6:3:5]. [40°] (N. a. W.); [50°] (Wroblewsky, A. 168, 187; Z. [2] 7, 210). From *o*-toluidine and bromine (Neville a. Winther, C. J. 37, 436). Forms unstable compounds with strong acids.

**Di-bromo-toluidine**  $C_6H_2(CH_3)(NH_2)Br_2$  [1:2:3:4]. [98°] (N. a. W.); [85°] (Wr.). By reducing the corresponding nitro-compound (Neville a. Winther, C. J. 37, 439; Wroblewsky, A. 168, 184). Does not combine with acids.

**Di-bromo-*m*-toluidine**  $C_6H_2Me(NH_2)Br_2$  [1:5:3:4]. [59°]. Formed by reducing the corre-

sponding di-bromo-nitro-toluene (Neville a. Winther, *C. J.* 37, 447).

*Acetyl derivative*  $C_6H_4(CH_3)(NHAc)Br_2$ . [163°].

**Di-bromo-*m*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:3:2:5]. [73°]. From the corresponding di-bromo-nitro-toluene [70°] by reduction. V. sol. alcohol; (Neville a. Winther, *C. J.* 37, 448).

*Acetyl derivative*  $C_6H_4(CH_3)(NHAc)Br_2$ . [145°].

**Di-bromo-*m*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:3:4:6]. [75°]. *Formation*.—1. Acetyl-*m*-toluidine is brominated. The product is boiled with alcoholic KOH and then distilled with dilute acid. This retains bromo-toluidine. By fractionally distilling the rest with steam, two di-bromo-*m*-toluidines [75°] and [35°], and one tri-bromo-toluidine [101°] may be isolated (Neville a. Winther, *C. J.* 37, 440).—2. By brominating the acetyl derivative of bromo-toluidine [32°], and removing acetyl by heating with  $H_2SO_4$  (2 vols.) and water (1 vol.).

*Acetyl derivative*  $C_6H_4(CH_3)(NHAc)Br_2$ . [168°].

**Di-bromo-*m*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:3:2:6]. [35°]. Prepared as above.

**Di-bromo-*m*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:3:5:6]. [86°]. Prepared by reducing di-bromo-nitro-toluene [105°] (Neville a. Winther, *C. J.* 37, 434). Formed also by heating the acetyl derivative with equal volumes of  $H_2SO_4$  and water.— $BHCl$ .

*Acetyl derivative*  $C_6H_4(CH_3)(NHAc)Br_2$ . [205°]. Formed by acetylation of the base; also from Br and bromo-acetyl-toluidine [168°].

**Di-bromo-*p*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:4:3:5]. [73°] (N. a. W.); [76°] (Wroblewsky). From *p*-toluidine and bromine (Wroblewsky, *A.* 168, 188; Neville a. Winther, *C. J.* 37, 436). From *p*-toluidine *m*-sulphonic acid and Br (Pechmann, *A.* 173, 216). Converted by  $N_2O_5$  into di-bromo-toluene [39°].

**Di-bromo-*p*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:4:2:5]. [85°]. Formed by reducing the corresponding nitro-compound [87°] (Neville a. Winther, *C. J.* 37, 445; Wroblewsky, *A.* 163, 185). Yields tri-bromo-toluene [111°].

**Di-bromo-*p*-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:4:2:6]. [88°]. Formed by reduction of the corresponding nitro-compound [57°].

**Di-bromo-toluidine**  $C_6H_4Me(NH_2)Br_2$  [1:4or6:2:3]. [53°]. From the corresponding di-bromo-nitro-toluene [57°] (N. a. W.).

**Tri-bromo-*o*-toluidine**  $C_6H_3Me(NH_2)Br_3$ . [106°]. Described by Gerver (*A.* 169, 379) as formed by brominating *o*-toluidine. Neville a. Winther (*C. J.* 37, 438) say that no such body is so formed.

**Tri-bromo-*m*-toluidine**  $C_6H_3Me(NH_2)Br_3$  [1:3:2:5:6]. [94°]. From the acetyl derivative by boiling with alcoholic potash.

*Acetyl derivative*  $C_6H_3(CH_3)(NHAc)Br_3$ . [181°]. From  $C_6H_3(CH_3)(NHAc)Br_2$  [1:3:2:5] [144°] and Br (Neville a. Winther, *C. J.* 37, 448).

**Tri-bromo-*m*-toluidine**  $C_6H_3Me(NH_2)Br_3$  [1:5:2:3:4]. [96°]. From its acetyl derivative by alcoholic KOH (N. a. W.).

*Acetyl derivative*  $C_6H_3(CH_3)(NHAc)Br_3$  [1:5:3:4:2]. [173°]. Formed by brominating  $C_6H_3(CH_3)(NHAc)Br_2$ .

**Tri-bromo-*m*-toluidine**  $C_6H_3Me(NH_2)Br_3$  [1:5:2:4:6]. [101°] (N. a. W.); [97°] (W.). Formed by brominating di-bromo-*m*-toluidine (Neville a. Winther, *C. J.* 37, 448; Wroblewsky, *A.* 168, 195).

**Tri-bromo-*p*-toluidine**  $C_6H_3Me(NH_2)Br_3$  [1:4:2:3:5]. [33°]. From the hydro-chloride of  $C_6H_3(CH_3)Br_2(NH_2)$  [1:2:4] and bromine-water (N. a. W.). Needles (from alcohol).

**Tri-bromo-*p*-toluidine**  $C_6H_3Me(NH_2)Br_3$  [1:4:5:6:2]. [118°]. Formed by reducing the corresponding nitro-compound [106°] by iron and acetic acid (Neville a. Winther, *C. J.* 39, 85).

**Tri-bromo-toluidine**  $C_6H_3Me(NH_2)Br_3$ . [113°]. From *p*-toluidine *m*-sulphonic acid and Br (Pechmann, *A.* 173, 217).

**Tri-bromo-toluidine**  $C_6H_3Me(NH_2)Br_3$ . [82°]. From *o*-bromo-toluene *m*-sulphonic acid by nitration, reduction and bromination (Schäfer, *A.* 174, 362; *B.* 7, 1355).

**Tri-bromo-toluidine**  $C_6H_3Me(NH_2)Br_3$ . [72°]. From *p*-bromo-toluene *o*-sulphonic acid by similar treatment (S.).

**Tetra-bromo-*m*-toluidine**  $C_6Me(NH_2)Br_4$  [1:3:2:4:5:6]. [224°]. From bromo-*m*-toluidine, [37°], aqueous HCl, and bromine (Neville a. Winther, *C. J.* 37, 449). White needles (from alcohol).

**Tetra-bromo-*p*-toluidine**  $C_6Me(NH_2)Br_4$  [1:4:2:3:5:6]. [227°]. From  $C_6H_4Me(NH_2)Br_2$  [1:4:2:6] dissolved in dilute HCl and treated with bromine-water (Neville a. Winther, *C. J.* 39, 85). Also from *p*-nitro-toluene,  $FeBr_3$ , and Br at 90° (Scheufelen, *A.* 231, 179).

**BROMO-TOLUIDINE SULPHONIC ACID** v. BROMO-AMINO-TOLUENE SULPHONIC ACID.

**DI-BROMO-TOLUQUINONE**  $C_6HMeBr_2O_2$  [85°]. Formed together with the tri-bromo-derivative by the action of bromine on toluquinone, and separated from it by crystallisation from dilute acetic acid in which it is the more soluble. Yellow needles; in sol. water and alcohol (Canfoneri a. G. Spica, *G.* 12, 472).

**Tri-bromo-toluquinone**  $C_6MeBr_3O_2$  [1:3:4:6:2:5]. [235°].

*Formation*.—1. From toluquinone and Br.—2. From tri-bromo-hydro-toluquinone and  $FeCl_3$ . 3. In small quantities, by heating cresol with  $H_2SO_4$ ,  $MnO_2$ , and KBr (*C.* a. S.).

*Properties*.—Pale yellow laminae; insol. water, sl. sol. alcohol. Aniline forms black crystalline  $C_6MeBr_3(NH_2)O_2$ . Aqueous KOH forms  $C_6MeBr_3(OH)O_2$  [197°] (Spica a. Magnanini, *G.* 13, 312).

**BROMO-*o*-DITOLYL**

[4:3or2:1]  $C_6H_3MeBr.C_6H_3Me$  [1:2]. [95° cor.]. From di-tolyl and Br (Carnelley a. Thomson, *C. J.* 47, 590). Purified by crystallisation from alcohol, from which an oily isomeride first separates. Oxidation gives bromo-terephthalic acid [309° cor.].

**Bromo-*op*-ditolyl** [4:1]  $C_6H_3Me.C_6H_3MeBr$  [1:2:3or6]. Oil; prepared as above. Oxidation gives bromo-diphenic acid [208°] and *c*-bromo-phthalic acid [197°].

**Di-bromo-ditolyl**  $C_6H_4Br_2$  [152°]. From Br and ditolyl in  $CS_2$  (Carnelley a. Thomson, *C. J.* 47, 591). Long hair-like needles; less soluble in alcohol than the preceding compound.  $CrO_3$  in HOAc gives  $C_6H_4Br_2O_2$  [166°] and  $C_6H_4Br_2O_2$  (?) [198°], neither of which compounds dissolves in KOH aq.

**BROMO-TOLYL-AMIDO-CHLORO-NAPH-THOQUINONE** v. **CHLORO-NAPHTHOQUINONE-BROMO-TOLUIDE**.

**DI-BROMO-o-TOLYL-AMIDO-PROPIONITRILE**  $C_8H_7MeBr_2CHMe.CN$ . [105°]. From *o*-tolyl-amido-propionitrile and Br (Stephan, *C. C.* 1886, 470).

**Di-bromo-*p*-tolyl-amido-propionitrile**  $C_8H_7MeBr_2CHMe.CN$ . [117°]. (S.).

**TETRA-BROMO-DI-TOLYL-AMINE**  $(C_8H_7MeBr_2)_2NH$ . [162°]. From Br and di-tolyl-nitrosamine in alcohol (Lehn, *B.* 13, 1514). Small needles.

**BROMO-*p*-TOLYL-BENZENE**  $C_9H_9Br$  i.e.  $[4:1] C_8H_7Br.C_6H_5Me$  [1:4]. *Bromo-phenyl-toluene*. [c. 30°]. A product of the bromination of *p*-tolyl-benzene. Oxidation gives bromodiphenyl-carboxylic acid [191°] and *p*-bromobenzoic acid (Carnelley a. Thomson, *C. J.* 51, 88).

**Bromo-*p*-tolyl-benzene**  $C_9H_9Br$  i.e.  $[1:2or3:4]$ . [129°]. From tolyl-benzene in  $CS_2$  by Br (Carnelley a. Thomson, *C. J.* 47, 586; 51, 87). Pearly plates, sl. sol. hot alcohol, v. e. sol. benzene. Oxidises to bromo-terephthalic acid [306° cor.].

**Di-bromo-*p*-tolyl-benzene**  $[4:1] C_8H_7Br.C_8H_7BrMe$  [1:2or3:4]. [115°]. From *p*-tolyl-benzene in  $CS_2$  and Br (Carnelley a. Thomson, *C. J.* 51, 89). Oxidation gives di-bromo-diphenyl-carboxylic acid [204°] and *p*-bromobenzoic acid.

**Di-bromo-tolyl-benzene**  $[4:1] C_8H_7Br.C_8H_7BrMe$  [1:3or2:4]. [150°]. Formed, together with the isomeric [115°] in brominating *p*-tolyl-benzene. Oxidation gives di-bromo-diphenyl-carboxylic acid [232°] and *p*-bromobenzoic acid.

**BROMO-TOLYLENE-*m*-DIAMINE**  $C_8H_7(CH_2)(NH_2)_2(Br)$  [1:2:4:5]. [104°]. Colourless plates. Sol. alcohol, ether, and  $CS_2$ . Prepared by bromination of the di-benzoyl-derivative of (1:2:4)-tolylene-diamine and subsequent saponification.

*Di-benzoyl-derivative* [214°]. White needles (Ruhemann, *B.* 14, 2658).

**Bromo-tolylene diamine**  $C_8H_7(CH_2)(NH_2)_2Br$ . [107°]. Formed by reducing bromo-di-nitro-toluene [104°] (Grete, *A.* 177, 262). —  $B''HCl$ . —  $B''HNO_3$ . —  $B''H_2SO_4$ . —  $B''H_2CO_3$ . This body is perhaps identical with the preceding.

**Bromo-tolylene-*o*-diamine**  $C_8H_7(CH_2)(NH_2)_2Br$  [1:2:3:4]. [59°]. Obtained by nitration and reduction of *p*-bromo-*o*-toluidine (Hübner a. Schüpphaus, *B.* 17, 775). Small colourless needles. V. sol. water, alcohol, and benzene.

**Salts**. —  $B'HCl$ : very soluble colourless needles. —  $B''H_2SO_4$ : colourless tables.

*Anhydro-formyl derivative* v. METHYNYL-BROMO-TOLYLENT-*o*-DIAMINE.

**BROMO-TOLYL-ETHANE** v. **BROMO-ETHYL-TOLUENE**.

***o*-BROMO-*a-m*-TOLYL-ETHYLENE**  $C_8H_7.CBr.CH_2$ . Formed by boiling *m*-tolyl di-bromo-ethane  $C_8H_7.CHBr.CH_2Br$  with alcoholic KOH. Very unstable body: begins to blacken even at 100° (Müller, *B.* 20, 1216).

***o*-Bromo-*a-m*-tolyl-ethylene**  $C_8H_7.CH.CHBr$ . *m*-Methyl-bromo-styrene. (212°). Oil. Formed by adding bromine to a warm solution of sodium

*m*-tolyl-acrylate (methyl-cinnamate) (Müller, *B.* 20, 1216).

**BROMO-TOLYL MERCAPTAN**  $C_8H_7MeBr.SH$ . [c. 7°]. (c. 245°). From *p*-bromo-toluene sulphochloride, tin, and HCl (Hübner a. Wallach, *Z.* [2] 5, 500).

**Bromo-tolyl mercaptan**  $C_8H_7MeBr.SH$ . (246°). From *o*-bromo-toluene *m*-sulphochloride [53°] by Zn and  $H_2SO_4$  (Hübner, *A.* 169, 41). Oil.

**DI-BROMO-DI-TOLYL-METHANE**  $C_{16}H_{14}Br_2$ . [115°]. From the hydrocarbon and Br (Weiler, *B.* 7, 1181).

**BROMO-*p*-TOLYL-*p*-METHYL-IMESATIN** v. *p*-METHYL-ISATIN-BROMO-*p*-TOLUIDE.

**TETRA-BROMO-*p*-TOLYL-(*β*)-NAPHTHYLAMINE**  $C_{16}H_{11}Br_4N$ . [169°]. Formed by bromination of *p*-tolyl-(*β*)-naphthyl-amine (Friedländer, *B.* 16, 2086). White silky needles. Sol. alcohol and ether.

**BROMO-DI-*α*-TOLYL-PROPIONIC ACID**  $C_{16}H_{19}MeBr.C(C_6H_5Me)Me.CO_2H$ . [111°]. Colourless crystals. Sol. alcohol, ether, &c. Formed by bromination of di-*α*-tolyl-propionic acid (Hauss, *B.* 15, 1178).

***αβ*-DI-BROMO-*m*-TOLYL-PROPIONIC ACID**  $C_{16}H_{19}MeBr_2$  i.e.  $[3:1] C_8H_7Me.CHBr.CHBr.CO_2H$ . [167°]. From *m*-methyl-cinnamic acid and Br (Müller, *B.* 20, 1215).

**DI-BROMO-DI-TOLYL-DI-SULPHIDE**  $(C_8H_7MeBr)_2S_2$ . [78°]. From *o*-bromo-tolyl mercaptan and dilute  $HNO_3$  (Hübner a. Post, *A.* 169, 42).

#### BROMO-UMBELLIFERON

*Methyl ether*  $[4 \frac{1}{2}] C_8H_7(OMe) \begin{matrix} CH:CB \\ \diagup \quad \diagdown \\ O \quad CO \end{matrix}$ .

[151°]. Formed by the action of bromine upon a solution of umbelliferon-methyl ether in  $CS_2$ . Long white needles; m. sol. hot alcohol and ether, sl. sol. cold alcohol and ether, insol. water; its dilute alcoholic solution has a green fluorescence. By alcoholic KOH it is converted into methoxy-coumarilic acid

$C_8H_7(OMe) \begin{matrix} CH:CO_2H \\ \diagup \quad \diagdown \\ O \quad \end{matrix}$

*Ethyl ether*  $C_8H_7(OEt) \begin{matrix} CH:CB \\ \diagup \quad \diagdown \\ O \quad CO \end{matrix}$  : [116°]

silvery tables; sol. boiling alcohol and ether, sl. sol. cold alcohol; its dilute alcoholic solution has a violet fluorescence. Analogous to the methyl-ether in its formation and properties (Will a. Beck, *B.* 19, 1782).

**Di-bromo-umbelliferon**

$C_8H_7Br(OH) \begin{matrix} CH:CB \\ \diagup \quad \diagdown \\ O \quad CO \end{matrix}$  (?).

*Methyl ether*  $C_8H_7Br(OMe) \begin{matrix} CH:CB \\ \diagup \quad \diagdown \\ O \quad CO \end{matrix}$  :

[251°]; formed by bromination of umbelliferon-methyl-ether dissolved in acetic acid; white glistening needles; sl. sol. alcohol.

*Ethyl ether*  $C_8H_7Br(OEt) \begin{matrix} CH:CB \\ \diagup \quad \diagdown \\ O \quad CO \end{matrix}$  :

[216°]; formed by bromination of umbelliferon-ethyl-ether in acetic acid (Will a. Beck, *B.* 19, 1786).

**Tri-bromo-umbelliferon**  $C_6H_2Br_3O_4$ . [194°]. From umbelliferon and bromine-water (Posen, *B.* 14, 2746; Mössner, *A.* 119, 261). The alcoholic solution shows greenish-yellow fluorescence.

**BROMO-UVITIC ACID**  $C_8H_7Br(CH_3)(CO_2H)_2$  [ $\alpha$ :1:3:5]. Prepared by oxidising bromo- $\omega$ , $\omega$ -di-oxy-megitylene with  $KMnO_4$  (Colson, *A. Ch.* [6] 6, 102). White crystals, carbonises at 285° without melting. Sol. alcohol.— $Na_2A''$ : tables.

**$\alpha$ -BROMO-*n*-VALERIC ACID**  $C_6H_7BrO_2$  i.e.  $C_6H_7CHBr.CO_2H$ . Formed by bromination of valeric acid (propyl-acetic acid) (Juslin, *B.* 17, 2504).

*Ethyl ether* EtA'. (191°); S.G.  $\frac{18}{4}$  = 1.226; colourless fluid.

**$\gamma$ -Bromo-*n*-valeric acid**

$CH_3CHBr.CH_2.CH_2.CO_2H$ . From allyl-acetic acid and conc.  $HBrAq$  at 0° (Messeschmidt, *A.* 208, 94). Boiling water or cold  $Na_2CO_3Aq$  convert it into the lactone of  $\gamma$ -oxy-valeric acid (*q. v.*).

**$\alpha$ -Bromo-isovaleric acid**

$(CH_3)_2CH.CHBr.CO_2H$  (chiefly). [40°]. (230°). From ordinary valeric acid and  $Br$  (Cahours, *A. Suppl.* 2, 74; Borodine, *A.* 119, 121; Fittig & Clark, *A.* 139, 199; Ley & Popoff, *A.* 174, 63; Schmidt, *A.* 193, 104). Formed also by the action of water on its bromide which is formed by treating isovaleric acid with  $Br$  and  $P$  (Volhard, *A.* 242, 163). Oil.

*Ethyl ether* EtA'. (186°). Is best purified by distillation with steam, the liquid is collected as soon as the oily drops sink under water (Lövén, *J. pr.* [2] 33, 112).

**Bromo-valeric acid**  $CMeEtBr.CO_2H$  or, possibly,  $CH_3CHBr.CHMe.CO_2H$  *Bromo-methyl-ethyl-acetic acid. Bromo-hydro-tiglic acid.* [66°]. From tiglic and angelic acids with conc.  $HBrAq$  at 0° (Kittig & Pagenstecher, *A.* 195, 108, 128; cf. p. 267). Monoclinic tables (from  $CS_2$ ); insol. cold water. Boiling water forms tiglic acid and some pseudo-butylene (*s*-di-methyl-ethylene).  $Na_2CO_3Aq$  produces chiefly pseudo-*n*-butylene. Sodium-amalgam forms methyl-ethyl-acetic acid.

**Bromo-valeric acid**  $C_6H_7BrO_2$  i.e.  $CMeEtBr.CO_2H$ ? From methyl-ethyl-acetic acid and  $Br$  at 160° (Böcking, *A.* 204, 23). Liquid. Should be identical with the preceding.

*Ethyl ether* EtA'. (185°). S.G.  $\frac{18}{4}$  1.2275. Decomposed by boiling  $Na_2CO_3Aq$  into  $\alpha$ -methyl- $\alpha$ -oxy-butyric ether  $CMeEt(OH).CO_2H$ .

**$\gamma$ -Di-bromo-*n*-valeric acid**

$CH_3Br.CHBr.CH_2.CH_2.CO_2H$ . [58°]. From allyl-acetic acid and  $Br$  in  $CS_2$  (Messerschmidt, *A.* 208, 100). Thin lamine. Converted by sodium-amalgam into allyl-acetic acid. Boiling water forms the lactone of bromo-oxy-valeric acid, and finally  $C_6H_8O_3$ .

**Di-bromo-valeric acid**  $CMe_2Br.CHBr.CO_2H$ . [106°]. Solidifies at 76°. From  $CMe_2CH.CO_2H$  and bromine (Ustinoff, *J. pr.* [2] 34, 483).

**Di-bromo-valeric acid**

$CH_3CHBr.CBrMe.CO_2H$ . [86°]. From tiglic acid and  $Br$  (Schmidt & Berendes, *A.* 191, 119); also from angelic acid and  $Br$  (Jaffé, *A.* 135, 293; Pagenstecher, *A.* 195, 123). Triclinic crystals (from  $CS_2$ ); insol. cold water. Converted by distillation or by sodium-amalgam

into tiglic acid (Demarçay, *B.* 8, 830). Boiling water decomposes its salts forming bromo-butylene (87°).— $KA'$ : insol. conc.  $KOH$  aq.

*Ethyl ether* EtA'. (185°). (J.).

**DI-BROMO-VALERIC ALDEHYDE**  $C_6H_7Br_2O$  i.e.  $CH_3CHBr.CBrMe.CHO$ . From tiglic aldehyde and  $Br$  (Lieben & Zeisel, *M.* 7, 55).

**BROMO-VALERO-LACTONE** *v.* **BROMO-OXY-VALERIC ACID**.

**BROMO-VALERYLENE**  $C_6H_7Br$ . (125°–130°). From valerylene dibromide and alcoholic  $KOH$  (Reboul, *A.* 135, 372). Forms a yellow pp. of  $C_6H_7Cu$  with ammoniacal cuprous chloride.

**BROMO-VANILLIC ACID** *v.* *Methyl derivative of Bromo-di-oxy-benzoic acid.*

**BROMO-VERATRIC ACID** *v.* *Methyl derivative of Bromo-di-oxy-benzoic acid.*

**BROMO-VINYL ACETATE**  $C_6H_7BrO_2$  i.e.  $CHBr.CH.OAc$ . From acetylene di-bromide and  $KOAc$  at 160° for 2 days (Sabanejeff, *A.* 216, 272). Crystals. Explode when quickly heated. Forms with bromine a compound  $C_6H_7Br_2O_2$ , which solidifies at 0°.

**$\omega$ -BROMO-*p*-VINYL-PHENOL**. *Methyl ether*  $C_6H_7(OMe).CH:CHBr$ . [55°]. From the di-methyl-ether of *as*-di-bromo-*p*-oxy-phenyl-propionic acid  $C_6H_7(OMe).CHBr.CHBr.CO_2Me$  by boiling with aqueous  $KOH$  (30 p.c.). Plates, of pleasant smell and taste (Eigel, *B.* 20, 2537).

*iso*-Bromo-*o*-vinyl-phenol

$C_6H_7(OH)Br.CH:CH_2$ . *Bromo-oxy-styrene.* (265°). Formed by distilling di-bromo-ethyl-phenol,  $C_6H_7(OH)Br.C_6H_4Br$  obtained by brominating *o*-ethyl-phenol (Suida & Plohn, *M.* 1, 180). Liquid, sl. sol. water. Gives a reddish-brown pp. with  $FeCl_3$ .

**Di-bromo-*o*-vinyl-phenol**. *Methyl ether*  $C_6H_7Br_2O$  i.e.  $C_6H_7(OMe)Br.C_6H_4Br$ . From the methyl derivative of tri-bromo-*oxy*-phenyl-propionic acid  $C_6H_7(OMe)Br.CHBr.CHBr.CO_2H$  and  $Na_2CO_3Aq$  (Perkin, *C. J.* 39, 418). Oil; slightly volatile with steam.

**BROMO-VINYL-PIPERIDINE**

$C_6H_{10}N(C_2H_5Br)$ . *Piper-ethyl-alkine-bromide*. Formed by heating the hydrobromide of piper-ethyl-alkine (oxethyl-piperidine) with 1 mol. of bromine at 100°–120°. On reduction with sodium-amalgam it yields ethyl-piperidine.— $B'HB$ : thin colourless prisms, sol. water,  $v$ . sl. sol. cold alcohol.— $B'HC$ .— $B_2H_2Cl_2PtCl_4$ .— $B'HC$ . $AuCl_3$ . (Ladenburg, *B.* 17, 154).

**BROMO-*o*-XYLENE**  $C_6H_4Br$  i.e.

$C_6H_4(CH_3)Br$  [1:2:4]. [0°]. (214° i. v.). Mol. w. 185°. S.G.  $\frac{18}{4}$  1.37. Formed by the action of bromine in presence of iodine upon *o*-xylene in the cold and in the dark (Jacobsen, *B.* 17, 2372; Schramm, *B.* 18, 1278).

**$\omega$ -Bromo-*o*-xylene**  $C_6H_4(CH_3).CH_2Br$ . *oxylol bromide*. [21°]. (217°) at 742 mm. S.G.  $\frac{23}{4}$  1.381. Colourless liquid. Prepared by the action of bromine-vapour upon boiling *o*-xylene; or in the cold upon *o*-xylene exposed to direct sunshine (Radziszewski & Wispek, *B.* 15, 1747; 18, 1281; Schramm, *B.* 18, 1278; Colson, *A. Ch.* [6] 6, 115).

**Bromo-*m*-xylene**  $C_6H_4(CH_3)Br$  [1:3:4]. (206°). Formed by the action of bromine upon cold *m*-xylene in the dark (Fittig, *A.* 147, 31; Schramm, *B.* 18, 1277).  $MeI$  and  $Na$  give *p*-cumene.

(8) **Bromo-*m*-xylene**  $C_6H_4Me_2Br$  [1:3:2]. (c. 206°). Liquid at  $-10^\circ$ . Obtained by adding 1 HCl solution of bromine to a solution of sodium *m*-xylene-(8)-sulphonate, which is prepared by debrominating di-bromo-*m*-xylene sulphonic acid  $C_6H_2Me_2Br_2(SO_3H)$  [1:3:4:6:2] with zinc-dust and aqueous ammonia. By methyl iodide and sodium it gives hemimellithene  $C_6H_2Me_2$  [1:2:3] (Jacobsen *A. Deike, B.* 20, 903).

**Bromo-*xylene***  $C_6H_4Me_2Br$  [1:3:5]. (201°). S.G. 22 1.362. Oil. From  $C_6H_4Me_2(NH_2)$  [1:3:4] *via*  $C_6H_4Me_2HHAc$ ,  $C_6H_4BrMe.NHAc$  and  $C_6H_4BrMe_2(NH_2)$  (Wroblewsky, *A.* 192, 215; *B.* 9, 495).

**Bromo-*m*-xylene**  $C_6H_4(CH_3).CH_2Br$ . *p*-Xylyl bromide. (215°) at 735 mm. (R. a. W.). (c. 218°) (C.). S.G. 22 1.371. Colourless liquid, with pungent vapour. Prepared by the action of the vapour of bromine on boiling *m*-xylene, or from Br (1 mol.) and cold *m*-xylene exposed to direct sunlight (Radziszewski *a. Wispek, B.* 15, 1745; 18, 1282; Schramm, *B.* 18, 1277; Colson, *A. Ch.* [6] 6, 117).

**Bromo-*p*-xylene**  $C_6H_4Br(CH_3)_2$  [2:1:4]. [10°]. (206° i.v.). Formed by the action of bromine upon cold *p*-xylene in the dark (Fittig *a. Jannasch, A.* 151, 283; 171, 82; *B.* 17, 2709; Jacobsen, *B.* 18, 356; Schramm, *B.* 18, 1276). Large plates.

***o*-Bromo-*p*-xylene**  $C_6H_4(CH_3).CH_2Br$ . *p*-Xylyl bromide. [36°]. (219°) at 710 mm. Long colourless needles. Sol. ether and chloroform. Pungent smell. Prepared by the action of bromine-vapour on boiling *p*-xylene, or of Br (1 mol.) upon cold *p*-xylene exposed to direct sunshine (Radziszewski *a. Wispek, B.* 15, 1743; *B.* 18, 1279; Schramm, *B.* 18, 1277).

**Di-bromo-*o*-xylene**  $C_6H_2(CH_3)_2Br_2$  [1:2:3:4?]. [7°]. (277°). S.G. 22 1.7812. Liquid at ordinary temperatures. Formed together with the isomeride [88°] by the action of bromine (2 mols.) in presence of iodine upon *o*-xylene (1 mol.) in the cold (Jacobsen, *B.* 17, 2376).

**Di-bromo-*o*-xylene**  $C_6H_2(CH_3)_2Br_2$  [1:2:4:5]. [88°]. (278°). Large trimetric plates, or long needles. V. sol. hot alcohol; v. sl. sol. alcohol at 0°. Formed as above (Jacobsen, *B.* 17, 2376).

***o*-Di-*o*-bromo-*xylene***  $C_6H_2(CH_3)_2Br_2$  [1:2]. *o*-Xylylene bromide. [95°]. S.G. 22 1.934. S. (ether) 20. S.H. (15°-40°) 183. Splendid large trimetric crystals. Prepared by heating *o*-xylene with bromine (2 mols.) at 130°-155°. Also by the action of Br (2 mols.) in the cold upon *o*-xylene (1 mol.) exposed to direct sunshine. Trimetric crystals; *a*:*b*:*c* = 8581:1:5014; v. sol. ether and chloroform. By boiling with a solution of  $Na_2CO_3$  for 3 hours it yields phthalylalcohol (Baeyer *a. Perkin, B.* 17, 123; Radziszewski *a. Wispek, B.* 18, 1281; Schramm, *B.* 18, 1278; Colson, *A. Ch.* [6] 6, 105; *C. R.* 101, 428; Perkin, jun., *C. J.* 53, 5).

**Di-bromo-*m*-xylene**  $C_6H_4(CH_3)_2Br_2$ . [72°]. (256°). From *m*-xylene and Br (Fittig, *A.* 147, 25; 156, 236).

**Di-bromo-*m*-xylene**  $C_6H_4(CH_3)_2Br_2$ . (252°). Liquid. From brominated *m*-xylylene by the diazo-reaction (Wroblewsky, *A.* 192, 216).

***o*,*o*'-Di-bromo-*m*-xylene**  $C_6H_4(CH_3)_2Br_2$  [1:3]. *Xylylene dibromide*. [77°]. S.G. 22 1.734; *sp*

(liquid) 1.615. S. (ligroin) 33. S.H. (15°-40°) 184. Formed by the action of bromine (2 mols.) in the cold upon *m*-xylene exposed to direct sunshine; also by adding Br (4 mols.) to *m*-xylene at 130°-180° (Schramm, *B.* 18, 1277; Radziszewski *a. Wispek, B.* 18, 1282; Colson, *A. Ch.* [6] 6, 109; *C. R.* 101, 428; Kipping, *C. J.* 53, 26). Prismatic needles (from  $CHCl_3$ ). Attacks the eyes. Converted by alcohol or boiling water into  $C_6H_4(CH_3)_2OH$ . Alkaline permanganate forms isophthalic acid.

**Di-bromo-*p*-xylylene**  $C_6H_4(CH_3)_2Br_2$  [1:4:2:5]. [76°]. (261°). From *p*-xylene, Br, and I. A small quantity of a liquid isomeride,  $C_6H_4(CH_3)_2Br_2$  [1:4:2:6] (?) is formed at the same time. Large triclinic crystals, plates, or flat needles (Jacobsen, *B.* 18, 358; Fittig, Ahrens *a. Mattheides, A.* 147, 26; Jannasch, *B.* 10, 1357).

***o*,*o*'-Di-bromo-*p*-xylene**  $C_6H_4(CH_3)_2Br_2$  [1:4]. *p*-Xylylene bromide. [141°]. (c. 215°). S. (ether) 2.65 at 20°. S.H. (15°-40°) 180. Formed by the action of bromine (2 mols.) in the cold upon *p*-xylene exposed to direct sunshine; or by the action of bromine-vapour on boiling *p*-xylene (Grimaux, *Z.* 1870, 394; Schramm, *B.* 18, 1277; Radziszewski *a. Wispek, B.* 15, 1744; 18, 1279; Löw, *A.* 231, 362; *B.* 18, 2072; Colson, *C. R.* 101, 428; *A. Ch.* [6] 6, 119; Kipping, *C. J.* 53, 31). Plates; sol.  $CHCl_3$ . Boiled with water (20 pts.) and lead nitrate (1 pt.) it forms terephthalic aldehyde and some terephthalic acid and *p*-aldehyde-benzoic acid. Fuming  $HNO_3$  acts similarly. Alcohol converts it into  $C_6H_4(CH_3)_2OH$ ; the rate of this saponification is less than with the *o*-, and still less than with the *m*-isomeride.

***cis*-Tri-bromo-*p*-xylene**  $C_6H_3(CHBr)_2(CH_3)Br$ . [106°]. Formed from *p*-xylene and impure bromine-vapour (Löw, *A.* 231, 363). Boiling water gives *o*-oxy-toluic aldehyde.

**Tetra-bromo-*o*-xylene**  $C_6H_2(CH_3)_2Br_4$ . [262°] (J.); [263°] (B.). (375°). From *o*-xylene and Br (Jacobsen, *B.* 17, 2378) in presence of  $AlBr_3$  (Blümlein, *B.* 17, 2192). Long glistening needles. V. sl. sol. hot alcohol; v. sol. hot benzene.

**Tetra-bromo-*p*-xylene**  $C_6H_2(CH_3)_2Br_4$ . [253°]. (355°). From *p*-xylene and Br (Jacobsen, *B.* 18, 359).

#### BROMO-*o*-XYLENE-SULPHONIC ACID

$C_6H_4(CH_3)_2(SO_3H)_2$  [1:2:3:4]. Formed by sulphonation of bromo-*o*-xylene. Crystals (containing aq). Very soluble in water, sparingly in cold dilute  $H_2SO_4$ .

**Salts.**— $NaA'$  1 aq; long fine needles, v. sol. hot water.— $KA'$  aq.— $BaA'$  3 aq; long thick prisms, sol. hot water.

**Amide**  $C_6H_4(CH_3)_2(Br)(SO_2NH_2)$  [213°]; long fine needles, v. sl. sol. water, sl. sol. cold alcohol (Jacobsen, *B.* 17, 2373).

**Bromo-*o*-xylene-sulphonic acid**  $C_6H_4(CH_3)_2Br(SO_3H)$ . Formed by the action of bromine upon an aqueous solution of *o*-xylene-sulphonic acid.— $BaA'$  4 aq; sparingly soluble needles.

**Amide**  $C_6H_4Me_2Br.SO_2NH_2$  [187°]; thick needles; v. sol. hot alcohol (Kelbe *a. Stein, B.* 19, 2137).

**Bromo-*m*-xylene sulphonic acid**  
 $C_6H_4(CH_3)_2Br(SO_3H)$  [1:3:2:4]. From di-bromo-*m*-xylene sulphamide by sodium-amalgam (Jacobsen a. Weinberg, *B.* 11, 1535).

**Amide**  $C_6H_4Me_2Br_2SO_2NH_2$ . [161° cor.].  
**Bromo-*m*-xylene sulphonic acid**  
 $C_6H_4Me_2Br(SO_3H)$  [1:3:6:4]. From  $C_6H_4Me_2Br_2(SO_3H)$  [1:3:4] by  $H_2SO_4$  or from  $C_6H_4Me_2Br$  [1:3:6] by fuming  $H_2SO_4$  (Veinberg, *B.* 11, 1062). From  $C_6H_4Me_2(NH_2)(SO_3H)$  by diazo-reaction (Sartig, *A.* 230, 335; Nölting a. Kohn, *B.* 19, 139; Limpriht, *B.* 18, 218). Slender needles, v. e. sol. water.

**Salts.**— $BaA'$  aq.— $NaA'$  aq.— $ZnA'$  2aq.— $CuA'$  2aq.

**Chloride** [61°]: large prisms.

**Amide** [194°]: small trimetric prisms.

**Bromo-*p*-xylene sulphonic acid**  
 $C_6H_4Me_2Br(SO_3H)$  [1:4:2:5]. Formed by heating diazo-*p*-xylene-sulphonic acid  $C_6H_4Me_2<\frac{N_2}{SO_3}>$  [1:4:2:5] with strong  $HBr$ .— $BaA'$  2aq: small white plates.

**Chloride**: [78°]; small white prisms.

**Amide**: [201°]; small white plates, v. sol. alcohol and ether, sl. sol. water, benzene, and chloroform (Nölting a. Kohn, *B.* 19, 141).

**Bromo-*p*-xylene-sulphonic acid**  
 $C_6H_4(CH_3)_2Br(SO_3H)$  [1:4:2:5]. Pearly plates or flat needles. Formed by sulphonation of bromo-*p*-xylene.

**Salts.**— $NaA'$  aq: long thin prisms, trimetric plates, or six-sided plates.— $BaA'$  2: small prisms or thin six-sided plates.

**Amide**  $C_6H_4(CH_3)_2Br_2(SO_2NH_2)$ . [206°], flat prisms, v. sol. not alcohol (Jacobsen, *B.* 17, 2378). This acid is perhaps identical with the preceding.

**Di-bromo-*m*-xylene sulphonic acid**  
 $C_6H_4(CH_3)_2Br_2(SO_3H)$  [1:3:4:6:2]. From di-bromo-*m*-xylene [72°] and fuming  $H_2SO_4$  (Jacobsen a. Weinberg, *B.* 11, 1534). Leaflets, sl. sol. cold water. Reduced by sodium-amalgam to (1,3,2)-*m*-xylene sulphonic acid.

**Salts.**— $BaA'$  2.— $NaA'$  2aq: leaflets.

**Chloride** [107°]: rhombic leaflets.

**Amide** [220°]: slender needles.

**BROMO-*m*-XYLENOL**  $C_6H_4(CH_3)_2Br(OH)$  [1:3:2:4]. From  $Br$  and *m*-xyleneol in  $HIOAc$ . Liquid (Jacobsen, *B.* 11, 24).

**Bromo-*p*-xyleneol**  $C_6H_4(CH_3)_2Br(OH)$  [1:4:2:5]. [87°]. From *p*-xyleneol and  $Br$  (Jacobsen, *B.* 11, 27).

**Di-bromo-*m*-xyleneol**  $C_6H_4(CH_3)_2Br_2(OH)$  [1:3:2:4:6] [73°] (J.).

**Di-bromo-*p*-xyleneol**  $C_6H_4(CH_3)_2Br_2(OH)$  [1:4:2:5]. [74°]. S. (alcohol) 200. From *p*-xyleneol and  $Br$  at 160° (Adam, *Bl.* [2] 41, 288). Needles; insol. water, but decomposed on boiling with it,  $HBr$  coming off.

**Tri-bromo-*o*-xyleneol**  $C_6H_3(CH_3)_3Br_3(OH)$  [1:2:4:5:6:3]. [184°]. Fine needles. Formed by bromination of *o*-xyleneol  $C_6H_3(CH_3)_3OH$  [1:2:3] (Thöl, *B.* 18, 2562).

**Tri-bromo-*o*-xyleneol**  $C_6H_3(CH_3)_3Br_3(OH)$  [1:2:3:5:6:4]. [169°]. From (1,2,4)-*o*-xyleneol. Felted needles (Jacobsen, *B.* 11, 28).

**Tri-bromo-*m*-xyleneol**  $C_6H_3(CH_3)_3Br_3(OH)$  [1:3:2:3:5:4]. [179°]. From (1,3,4)-*m*-xyleneol (J.). Long needles.

**Tri-bromo-*m*-xyleneol**  $C_6H_3(CH_3)_3Br_3(OH)$  [1:3:2:4:5:5]. [166°]. Fine white needles. From *m*-xyleneol  $C_6H_3(CH_3)_3OH$  [1:3:5] (Nölting a. Forel, *B.* 18, 2679; cf. Thöl, *B.* 18, 362).

**Tri-bromo-*p*-xyleneol**  $C_6H_3(CH_3)_3Br_3(OH)$  [175°]. Golden yellow needles (Jacobsen, *B.* 11, 26).

**BROMO-*m*-XYLIDINE**  $C_6H_4BrN$  i.e.  $C_6H_4(CH_3)_2Br(NH_2)$  [1:3:5:4]. [97°]. From acetyl-*m*-xylidine by bromination and saponification. Minute needles (from dilute alcohol). Converted by the diazo-reaction into *s*-bromo-xylene (Gexz, *B.* 3, 225; Wroblewsky, *A.* 192, 215).

**Di-bromo-*o*-xylidine**  $C_6H_4(CH_3)_2Br_2NH_2$  [1:2:4:5:3]. [103°]. Obtained by reduction of the corresponding nitro-compound with iron and acetic acid. Colourless needles. V. sol. alcohol ether, and acetic acid. Does not form salts. By sodium-amalgam it is debrominated (Thöl, *B.* 18, 2562).

**Di-bromo-*m*-xylidine**  $C_6H_4(CH_3)_2Br_2(NH_2)$ . From acetyl-*m*-xylidine by brominating and saponifying (Grenz, *B.* 3, 225). Needles (from alcohol).

**Di-bromo-*p*-xylidine**  $C_6H_4Me_2Br_2(NH_2)$  [1:4:5:2:2]. [65°]. Formed by acidifying an alkaline solution of (1 mol. of) *p*-xylidine-sulphonic acid  $C_6H_4Me_2(NH_2)(SO_3H)$  [1:4:2:5] and (2 mols. of) bromine. Also formed by bromination of *p*-xylidine (Nölting a. Kohn, *B.* 19, 142).

**BROMO-*m*-XYLIDINE-SULPHONIC ACID**  
 $C_6H_4Me_2Br(NH_2)(SO_3H)$  [1:3:5:2:1:6]. Small white needles. Sol. hot, v. sl. sol. cold water, insol. alcohol. Formed by bromination of *m*-xylidine-sulphonic acid  $C_6H_4Me_2(NH_2)(SO_3H)$  [1:3:1:6] (Nölting a. Kohn, *B.* 19, 140).

**Bromo-*p*-xylidine-sulphonic acid**  
 $C_6H_4Me_2Br(NH_2)(SO_3H)$  [1:4:5:2:1:6]. Small white plates. Nearly insoluble in cold water. Formed by bromination of *p*-xylidine-sulphonic acid  $C_6H_4Me_2(NH_2)(SO_3H)$  [1:4:6:2].— $AK$  (Nölting a. Kohn, *B.* 19, 143).

**DI-BROMO-*m*-XYLOQUINONE**  $C_6Br_2Me_2O_2$  [1:3:4:6:2:5]. [174°]. From mesitol,  $C_6H_4Me_3(OH)$  and  $Br$  in water (Jacobsen, *A.* 195, 271). Golden laminae (from alcohol), insol. water and  $Na_2CO_3$  aq, decomposed by  $KOH$  aq.

**Di-bromo-*p*-xyloquinone**  $C_6Br_2Me_2O_2$  [1:4:5:2:3:6]. [181°]. Formed by the action of bromine upon *p*-xyloquinone under water. Thin golden plates. Insol. water and cold alcohol; sol. ether and benzene (Carstanjen, *J. pr.* [2] 23, 434).

**BRONZE v. COPPER, ALLOYS OF.**

**BRUCINE**  $C_{23}H_{27}N_3O_4$  4aq. [105° hydrated]; [178° anhydrous] (Claus, *B.* 14, 773); [151°] (Blyth). S. 12 at 15°; 2 at 100°.  $[\alpha]_D^{20} = -85^\circ$  (in alcohol);  $-110^\circ$  to  $-127^\circ$  (in  $CHCl_3$ ) (Oudemans, *A.* 166, 69).

**Occurrence.**—Together with strychnine in *nux vomica* (the seeds of *Strychnos nux vomica*), in the bean of *St. Ignatius* (the seed of *Strychnos Ignatii*), in the wood of *Strychnos colubrina*, in *upas tiende*, extracted from the bark of *S. tiende*, and in the bark of *Strychnos nux vomica* (*False Angustura bark*) (Pelletier a. Caventou, *A. Ch.* [2] 12, 118; 26, 53; Pelletier a. Dumas, *A. Ch.* [2] 24, 176; Corriol, *J. Ph.* 11, 495; Liebig, *A. Ch.* [2] 47, 172; *A.* 26, 50; Regnault, *A. Ch.* [2] 68, 113). Brucine, free from strychnine,

occurs in the bark of *Strychnos Ligustrina* (*Bidara Lauti*) (Greenish, *Ph.* [3] 9, 1013).

**Preparation.**—Nux vomica seeds (56 lbs.) are powdered and exhausted with alcohol, to which one-sixth part of water has been added. The alcohol is boiled off and the residue treated with water (40 lbs.) containing  $\text{H}_2\text{SO}_4$  (1 lb.). The filtrate is neutralised with  $\text{Na}_2\text{CO}_3$ . The pp. is collected after a few hours, dissolved in chloroform, and the solution shaken with very dilute  $\text{H}_2\text{SO}_4$ , which dissolves brucine. The solution is placed under a bell jar together with a beaker containing ammonia so that neutralisation proceeds very slowly. The crystalline pp. is extracted with dilute alcohol, which dissolves brucine, and the solution allowed to evaporate. The brucine, containing strychnine, is dissolved in dilute  $\text{H}_2\text{SO}_4$ , and the faintly alkaline solution mixed with KI. The brucine hydriodide that is ppd. is crystallised several times from alcohol. It is then shaken with aqueous  $\text{Na}_2\text{CO}_3$  and chloroform, the chloroform is then shaken with dilute acid and the base pp. with ammonia (W. A. Shenstone, *C. J.* 39, 453).

**Properties.** Monoclinic efflorescent prisms (from dilute alcohol); v. sol. alcohol, chloroform, and essential oils, insol. ether and fatty oils. Feebly alkaline to litmus or phenolphthalein (Plugge, *Ar. Ph.* [3] 25, 45). It is levorotatory, the extent of rotation depending upon the nature of the solvents and the concentration of the solution. In presence of free acids  $[\alpha]_D$  varies from  $-29^\circ$  to  $-36.5^\circ$  (Tykociner, *R. T. C.* 1, 144). Commercial brucine usually contains strychnine, but the colour which strychnine gives with oxidising agents is masked by the presence of brucine. The strychnine may, however, be detected by adding dilute  $\text{HNO}_3$  and then extracting the strychnine with chloroform in presence of excess of KOH (Shenstone, *Ph.* [3] 8, 445; Hanriot, *C. R.* 97, 267). Brucine is affected by heating with acids, alkalis, or even water, and hence much is lost by the usual method of preparation, but the products being usually amorphous, the unaltered brucine is easily separated in a pure state.

**Colour tests.**—*V. p.* 124. The most characteristic is the red colour with nitric acid, which, after warming, is turned violet by excess of ammonium sulphide (v. also Cotton, *Z.* [2] 5, 728; *J. Ph.* [4] 10, 18; Luck, *Z.* [3] 6, 275; Le Linde, *C. N.* 37, 98; Flückiger, *Fr.* 15, 312; Hager, *Fr.* 11, 201; Dragendorff, *Fr.* 18, 108; Pandis, *C. C.* 1872, 410; Struve, *Fr.* 12, 16; Buckingham, *Ph.* [3] 3, 881).

**Reactions.**—1. Brucine (60 g.) heated with alcohol (600 c.c.) and NaOH (30 g.) at  $100^\circ$  for 12 hours forms a solution which, after neutralisation with  $\text{CO}_2$ , filtration and evaporation, leaves a varnish containing some crystals. The crystals (7 g.) separated from the varnish by washing with water and purified by solution in very little dilute HCl and ppn. by  $\text{NH}_3$  are thrown down as microscopic crystals of  $\text{C}_{22}\text{H}_{29}\text{N}_3\text{O}_5$  ( $2\frac{1}{2}$  g.). This gives a yellow colour with  $\text{HNO}_3$ ; a pp. with bromine, and on boiling a magenta colour. An ammoniacal solution turns purple in air and finally green (Shenstone).—2.  $\text{HNO}_3$  (S.G. 1.2 to 1.4) forms a red solution, producing 'cacotheline'  $\text{C}_{22}\text{H}_{29}\text{N}_3\text{O}_{10}$ , oxalic acid, and methyl nitrite (Strecker, *A.* 91,

76; Hanssen, *B.* 20, 411).  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  oxidise cacotheline to  $\text{C}_{22}\text{H}_{29}\text{N}_3\text{O}_{10}$ , which is also formed by the oxidation of brucine.—3. Brucine (1 mol.) heated with  $\text{HCl}$  at  $140^\circ$  gives off  $\text{MeCl}$  (between 1 and 2 mol.). Brucine is therefore possibly  $\text{C}_{22}\text{H}_{29}(\text{OMe})\text{N}_3\text{O}_5$ , strychnine being  $\text{C}_{22}\text{H}_{29}(\text{OH})\text{N}_3\text{O}_5$  (Shenstone, *C. J.* 43, 101; cf. Hanssen, *B.* 17, 226).—4. Yields on distillation with potash several pyridine bases. Amongst others ( $\beta$ )-di-methyl pyridine and ( $\delta$ )-tri-methyl-pyridine, quinolin tetrahydride, together with probably a di-methyl-pyridine (Oechsner de Coninck, *A. Ch.* [5] 27, 507; *C. R.* 99, 1077; *Bl.* [2] 42, 100).—5. Distilled *in vacuo* with zinc dust it yields carbazol (Lämbisch a. Schoop, *M.* 7, 613).—6. Alkaline  $\text{KMnO}_4$  gives off about half the nitrogen in the free state (Wanklyn a. Chapman, *C. J.* 21, 161).—7.  $\text{ICl}$  forms a light flocculent pp. in solutions of salts of brucine (Dittmar).

**Salts.**— $\text{BrHCl}$ : crystalline tufts, m. sol. water.— $\text{BrHClH}_2\text{Cl}_2$ : long needles (from alcohol).— $\text{Br}_2\text{H}_2\text{PtCl}_6$ : yellow pp.— $\text{BrHCl}$  aq: rectangular laminae or very short prisms; m. sol. hot water.— $\text{BrHI}$ : brown violet needles (Jörgensen, *A. Ch.* [1] 11, 114; *J. pr.* [2] 3, 160).— $\text{Br}_2\text{H}_2\text{I}_4$ : unstable orange needles.— $\text{BrHNO}_3$  2aq: four-sided prisms; less soluble in water than strychnine nitrate.  $\text{Br}_2\text{H}_2\text{SO}_4$  7aq: long needles, v. sol. water, sl. sol. alcohol.— $\text{Br}_2\text{H}_2\text{S}_2\text{O}_5$  5aq: *S.* 1 at  $15^\circ$  (How, *N. Ed. P. J.* [new] 98).— $\text{Br}_2\text{H}_2\text{S}_3$  6aq: [125°]; insoluble yellow needles, formed by atmospheric oxidation of an alcoholic solution containing  $\text{H}_2\text{S}$  (Schmidt, *A.* 180, 296; *B.* 8, 1267; 10, 838, 1288).— $\text{Br}_2\text{H}_2\text{S}_{12}$ .— $\text{Br}_2\text{H}_2\text{PO}_4$  2aq (Anderson, *P. M.* [3] 33, 163).— $\text{Br}_2\text{H}_2\text{FeCy}_2$  2aq: hygroscopic needles, m. sol. hot water (Brandis, *A.* 66, 266).— $\text{Br}_2\text{H}_2\text{FeCy}_4$  4aq.— $\text{BrHFeCy}_3$ : white powder (Holst a. Beckurts, *Ar. Ph.* [3] 25, 313).— $\text{Br}_2\text{H}_2\text{FeCy}_6$  6aq.— $\text{Br}_2\text{H}_2\text{CoCy}_{10}$  10aq (Lee, *Am. S.* [2] 2, 44).— $\text{Br}_2\text{H}_2\text{NiCy}_4$  (L.).— $\text{BrHCyS}$ : scales, sol. water.—Periculate: needles (Bödeker, *A.* 71, 64; Langlois, *A. Ch.* [3] 31, 278).—Nitroprusside: *S.* 15 at  $15^\circ$  (Davy, *Ph.* [3] 11, 756). Acetate: crystalline, but gummy if impure (Shenstone).—Dextro-tartrates:  $\text{Br}_2\text{C}_2\text{H}_2\text{O}_4$  5aq.— $\text{Br}_2\text{C}_2\text{H}_2\text{O}_6$  8aq.  $\text{Br}_2\text{C}_2\text{H}_2\text{O}_8$  11aq.  $\text{Br}_2\text{C}_2\text{H}_2\text{O}_{10}$  14aq (Pasteur, *A. Ch.* [3] 38, 472).— $\text{Br}_2\text{C}_2\text{H}_2(\text{SbO})_6$  (Stenhouse, *A.* 129, 26).

**Methylo-iodide**  $\text{BrMeI}$  8aq: laminae (from water); resolidified by boiling KOH (Stahlschmidt, *P.* 108, 513).— $\text{BrMeI}_2$ .— $\text{BrMeI}_3$ .—**Methylo-bromide**  $\text{BrMeBr}$  2aq.—**Methylo-chloride**  $\text{BrMeCl}$  5aq: v. sol. water and alcohol.— $\text{Br}_2\text{MePtCl}_6$ .— $\text{BrHAnCl}_3$ .—**Methylo-sulphate**  $\text{Br}_2\text{MeSO}_4$  8aq: radiate crystalline mass, v. sol. water.  $\text{BrMeSO}_4$  2aq.—**Methylo-nitrate**  $\text{BrMeNO}_3$  2aq. The physiological action of these salts has been studied by Crum Brown (*T. F.* 25).

**Ethylo-iodide**  $\text{BrEtI}$  4aq: not decomposed by KOH but converted by moist  $\text{Ag}_2\text{O}$  into a very soluble alkaline hydroxide.— $\text{BrEtI}_2$ .— $\text{BrEtI}_3$  aq.—**Ethylo-platino-chloride**  $\text{Br}_2\text{EtPtCl}_6$ : silky needles (Gunning, *J. pr.* 67, 46).—**Bromo-ethylo-bromide**  $\text{Br}_2\text{C}_2\text{H}_4\text{Br}_2$  3aq: from brucine and ethylene bromide at  $100^\circ$ ; forms furcate groups of nacreous laminae (from water),  $\text{AgNO}_3$  pps. half the Br. Moist  $\text{Ag}_2\text{O}$

forms the *vinyl-o-bromide*  $B'C_2H_3OH$  which is strongly alkaline; two of its salts are  $B'_2(C_2H_3Cl)_2PtCl_6$  and  $B'C_2H_3SO_3H_8aq.$ —*Bromo-ethyl-platinochloride*  $B'_2(C_2H_3Br)_2PtCl_6$  (Schad, A. 118, 207).

*Allylo-iodide*  $B'C_3H_5I_{aq.}$ — $B'C_3H_5I_2$ — $B'C_3H_5I_{aq.}$ —*Allylo-platino-chloride*  $B'_2(C_3H_5Cl)_2PtCl_6$ —*Iso-allylo-chloride*  $B'_2(C_3H_5Cl)_2PtCl_6$ —*Iso-allylo-iodides*  $B'C_3H_5I_2$ — $B'C_3H_5I_{aq.}$

*Bromo-brucine*  $C_{22}H_{23}BrO_4$ . Formed by adding an alcoholic solution of Br to an aqueous solution of brucine sulphate. Small needles (Laurent, A. Ch. [3] 24, 314; cf. Beckurts, B. 18, 1238).

*Nitro-brucine*  $C_{22}H_{23}(NO_2)_2O_4$ . Formed by nitration of brucine-methyl-iodide suspended in absolute alcohol. Large red trigetric crystals. Carbonises at about  $210^\circ$  without melting; sol. water. Salts.— $B'INO_2$ : glistening yellow needles, v. sol. water, sl. sol. alcohol and ether.— $B'_2H_2Cl_2PtCl_6$ : fine yellow needles (Hanssen, B. 19, 520).

*Amido-brucine*  $C_{22}H_{23}(NH_2)_2O_4$ . Formed by reduction of nitro-brucine with tin and HCl. V. sol. water. Not isolated.  $FeCl_3$  produces a green colouration changing to brown. Very dilute  $K_2Cr_2O_7$  produces a fugitive blue-violet colour. Strong  $HNO_3$  gives a yellow solution which is turned red by  $SnCl_2$ — $B''H_2Cl_2$ : colourless prisms.— $B''H_2Cl_2PtCl_6$ : yellow amorphous pp. (Hanssen, B. 19, 523).

*Dinitro-brucine*  $C_{22}H_{23}(NO_2)_2O_4$ . Prepared by the action of  $HNO_3$  on an alcoholic solution of brucine. Red amorphous powder. V. sol. water, sl. sol. alcohol, insol. ether.— $(B'HCl)_2PtCl_6$ : yellow pp. (Claus a. Röhre, B. 14, 765).

**BRYONIN**  $C_{28}H_{38}O_{10}$ . An amorphous bitter substance in the root of the red-berried bryony (*Bryonia dioica*) from which it may be extracted by boiling water. It appears to be resolved by dilute  $H_2SO_4$  into glucose and two amorphous bodies, bryoretin  $C_{21}H_{28}O_7$  sol. ether, and hydro-bryoretin  $C_{21}H_{28}O_8$  insol. ether (Brandes a. Firnhaber, Brandes' Ar. Ph. 3, 356; Walz, C. C. 1859, 6).

**BUCHU.** The leaves of several species of *Barosma* growing at the Cape contain a volatile oil and a crystalline substance [ $85^\circ$ ] (Flückiger, Ph. [3] 4, 689; Jones, Ph. [3] 9, 673).

**BURETTE** v. ANALYSIS, p. 248.

**BUTALANINE** v. AMIDO-BUTYRIC ACID.

**n-BUTANE**  $C_4H_{10}$  i.e.  $CH_3CH_2CH_2CH_3$ . *Di-ethyl. Methyl-propyl. Butyl-hydride*. Mol. w. 58. ( $1^\circ$ ) (Butlerow, Z. 1867, 363). S.G.  $\frac{1}{4}$  0.60. V.D. 2.11 (calc. 2.01) (Ronalds, C. J. 18, 54; Pelouze a. Cahours, A. Ch. [4] 1, 5). S. (gas in alcohol) 18 at  $14^\circ$ . Occurs in petroleum (R.). Formed by the action of Zn on EtI at  $150^\circ$  (Frankland, A. 77, 221; Schöyen, A. 130, 238). Also, together with butylene, by heating butyl alcohol with  $ZnCl_2$  (Wurtz, A. 93, 112). Prepared by the action of sodium-amalgam on EtI (Löwig, J. 1860, 397).

**Iso-butane**  $(CH_3)_3CH$ . *Trimethyl-methane. Secondary butane.* ( $-17^\circ$ ). H.F. p. 42,450. H.F. v. 40,180 (Z.). Prepared by slowly pouring *tert*-butyl iodide into water containing zinc, the equation being  $2(CH_3)_3CI + H_2O + Zn_2 = 2(CH_3)_3CH + ZnO + ZnI_2$ . Also from iso-butyl

iodide and  $AlCl_3$  at  $120^\circ$  (Köhlein, B. 16, 562). Colourless gas. Chlorine converts it into  $(CH_3)_3CCl$  (Butlerow, A. 144, 10). Br at  $100^\circ$  forms di-bromo-butane (Carius, A. 126, 195). Excess of Br at  $300^\circ$  forms  $C_2Br_4$  (Merz a. Weith, B. 11, 2244).

**BUTANE CARBOXYLIC ACID** v. BUTYRIC ACID.

**Butane di-carboxylic acid** v. PROPYL-MALONIC ACID, ISO-PROPYL-MALONIC ACID, METHYL ETHYL-MALONIC ACID, ETHYL-SUCCINIC ACID, TWO DI-METHYL-SUCCINIC ACIDS, ADIPIC ACID,  $\alpha$ -METHYL-GLUTARIC ACID, and  $\beta$ -METHYL-GLUTARIC ACID.

**Butane  $\alpha,\omega$ -tricarboxylic acid**  $C_4H_6O_6$ .  $MeCH_2CH(CO_2H)CH(CO_2H)_2$ . *Ethyl. Methyl-tricarboxylic acid.* [ $119^\circ$ ]. Got by saponifying the ether with alcoholic potash (Polko, A. 242, 115). White rhombic crystals. V. e. sol. water, alcohol, ether, acetone, v. sol. chloroform. Salts.— $A'''Ba_2$ , insol. water and alcohol.— $A'''Ag$ ,  $1\frac{1}{2}aq$ , sl. sol. water.— $A'''CaH_2$ , insol. alcohol, v. sol. water.— $A'''CaH_2$ ,  $2\frac{1}{2}aq$ .— $A'''Ca_2$ , hygroscopic.— $A'''Zn$ ,  $6aq$ , v. e. sol. water, insol. alcohol.— $A'''Sr_2$ ,  $6aq$ .

*Ethyl ether*  $MeCH_2CH(CO_2Et)CH(CO_2Et)_2$ . [ $276^\circ$ ]. ( $189^\circ$  at 60 mm.). S.G.  $\frac{1}{4}$  1.065. Formed by acting on sodium malonic ether with  $\alpha$ -bromobutyric ether in alcoholic solution (P.).

**Butane  $\alpha,\beta$ -tri-carboxylic acid**  $CH_3CH(CO_2H)C(CO_2H)_2CH_3$ . *Butenyl-tricarboxylic acid.* [ $157^\circ$ ]. V. sol. water, alcohol and ether. On warming it yields s-di-methylsuccinic anhydride [ $87^\circ$ ] (Bischoff a. Rach, A. 234, 54). Salts.— $Ba_2A'''$ .— $Ca_2A'''$ .

*Ethyl ether*  $Et_2A'''$ . ( $c$ .  $190^\circ$ ) at 50-60 mm.; ( $273^\circ$ - $275^\circ$ ) at ordinary pressure. Liquid. Formed by the action of  $\alpha$ -bromo-propionic ether upon sodio-methyl-malonic ether. By boiling with HCl it is converted into s-di-methylsuccinic acid [ $189^\circ$ ] (Leuckart, B. 18, 2346).

**Iso-butane tri-carboxylic acid**  $Me_2C(CO_2H)CH(CO_2H)_2$ . [ $120^\circ$ ]. Prepared by saponifying the ether with alcoholic potash (Barnstein, A. 242, 128). Needle-shaped crystals (from water). V. e. sol. water, alcohol, ether, acetone, v. sl. sol. chloroform, benzene, petroleum ether, carbon disulphide. Decomposed by boiling with water, giving off  $CO_2$ . Salts.— $K_2A'''$  2aq. Quadratic prisms: v. e. sol. water, insol. alcohol.— $Ca_2A'''$ ,  $9aq$ : m. sol. water.— $CaA'''$ ,  $2aq$ : v. e. sol. water.— $Sr_2A'''$ ,  $7aq$ .

*Ethyl ether*  $Et_2A'''$ . ( $181^\circ$ - $185^\circ$ ) at 30-40 mm.; ( $279^\circ$ - $281^\circ$ ) at ordinary pressure (L.); ( $273^\circ$ ) (B.). S.G.  $\frac{1}{4}$  1.061. Liquid. Formed by the action of  $\alpha$ -bromo-isobutyric ether upon sodio-malonic ether. By boiling with HCl it is converted into  $\alpha$ -di-methylsuccinic acid [ $139^\circ$ ] (Leuckart, B. 18, 2350; Barnstein, A. 242, 126).

**Butane  $\alpha,\omega,\gamma$ -tetra-carboxylic ether**  $C_8H_{16}O_8$  i.e.  $(CO_2H)_2CH_2CH_2CH_2CH_2CO_2H$ . ( $275^\circ$ - $280^\circ$ ) at 225 mm. Formed, together with trimethylene dicarboxylic acid, by the action of ethylene bromide on sodium malonic ether (Perkin, jun., C. J. 51, 17; B. 19, 2038). The yield is very small. The corresponding acid splits up when heated into  $CO_2$  and adipic acid. By treatment with sodium ethylate it gives a di-sodio-derivative which by the action of bromine yields tetra-  

$$\begin{array}{c} CH_2(CO_2Et)_2 \\ | \\ CH_2C(CO_2Et)_2 \end{array}$$
 methylene-tetra-carboxylic ether

**Iso-butane tetra-carboxylic ether**  
 $(\text{CO}_2\text{Et})_2\text{CH}(\text{CHMe})_2\text{CH}(\text{CO}_2\text{Et})_2$ . (c. 211°) at 20 mm. A by-product in the preparation of ethylidene-malonic ether from aldehyde and malonic ether; it is formed by the addition of malonic ether to ethylidene-malonic ether  $\text{CH}_2=\text{CH}:\text{C}(\text{CO}_2\text{Et})_2$  (Kommenos, A. 218, 158; Claisen, J. pr. [2] 35, 414). The corresponding acid is split up by distillation into  $\text{CO}_2$  and  $\beta$ -methyl-glutaric acid  $\text{CO}_2\text{H}(\text{CH}_2)_2\text{CHMe}(\text{CH}_2)_2\text{CO}_2\text{H}$ .

**Butane  $\alpha\alpha\beta\beta$ -tetra-carboxylic ether**  
 $(\text{CO}_2\text{Et})_2\text{CMe}(\text{CO}_2\text{Et})_2$ . Di-methyl-acetylene-tetra-carboxylic ether. S.G.  $\frac{1}{4}$  1.114. From sodio-methyl-malonic ether by the action of iodine on chloro-methyl-malonic ether. From sodio-ethallo tetra-carboxylic ether and MeI (Bischoff a. Rach, B. 18, 1202; A. 234, 70).

**Butane tetra-carboxylic ether**  
 $\text{CH}(\text{CO}_2\text{H})_2\text{C}(\text{C}_2\text{H}_5)(\text{CO}_2\text{Et})_2$ . Ethyl-acetylene-tetra-carboxylic acid. Thick colourless oil; formed by the action of chloro-malonic ether on sodio-ethyl-malonic ether (Bischoff a. Rach, B. 17, 2785).

**Butane hexa-carboxylic ether**  
 $\text{CO}_2\text{Et}(\text{CH}_2)_2\text{C}(\text{CO}_2\text{Et})_2\text{C}(\text{CO}_2\text{Et})_2\text{CH}_2\text{CO}_2\text{Et}$ . [57°]. Six-sided tables. From sodium ethane tri-carboxylic ether  $(\text{CO}_2\text{Et})_3\text{CNa}(\text{CH}_2)_2\text{CO}_2\text{Et}$  by the action of iodine or of  $(\text{CO}_2\text{Et})_2\text{CCI}(\text{CH}_2)_2\text{CO}_2\text{Et}$  (Bischoff, B. 16, 1046; 17, 2786).

**ISO-BUTANE SULPHONIC ACID**  
 $(\text{CH}_3)_2\text{CH}(\text{CH}_2)_2\text{SO}_3\text{H}$ . From iso-butane sulphochloride by zinc dust (Pauly, B. 10, 912). Liquid. Reduced by nascent hydrogen to isobutyl mercaptan.— $\text{ZnA}'_2$ . Plates (from alcohol).  
**n-BUTANE SULPHONIC ACID**  $\text{C}_4\text{H}_9\text{SO}_3\text{H}$ . Formed by the action of  $\text{HNO}_3$  on n-butyl mercaptan (Grabowsky, A. 175, 341). Thick syrup, v. sol. water and alcohol, m. sol. ether.— $\text{AgA}'_2$ : plates.— $\text{PhA}'_2$ : plates, sl. sol. alcohol.— $\text{PbA}'_2 \cdot 2\text{Pb}(\text{OH})_2$ : crystalline powder, sl. sol. water.— $\text{BaA}'_2 \cdot \text{aq}$ : plates.— $\text{CaA}'_2 \cdot 2\text{aq}$ .— $\text{NaA}'_2$ : plates.

**iso-butane sulphonic acid**  
 $(\text{CH}_3)_2\text{CH}(\text{CH}_2)_2\text{SO}_3\text{H}$ . From iso-butyl mercaptan and  $\text{HNO}_3$  (Mylius, B. 5, 978). Syrup. Its salts are v. sol. water.— $\text{AgA}'_2$ : scales.— $\text{BaA}'_2$ : needles.

**Chloride**  $\text{C}_4\text{H}_9\text{SO}_2\text{Cl}$  (190°) (Pauly, B. 10, 942).

**ISO-BUTENYL ACETATE**  $\text{CH}_3\text{CMe}(\text{CH}_2)\text{OAc}$  (120°) (Scheschukoff, J. R. 16, 502).

**BUTENYL ALCOHOL**  $\text{C}_4\text{H}_9\text{O}$  i.e.  $\text{CH}_3\text{CH}(\text{CH}_2)\text{CH}_2\text{OH}$ . (117°). A product of the action of iron and acetic acid upon crotonic and tri-chloro-butyric aldehydes (Lieben a. Zeisel, M. 1, 825).  $\text{HI}$  gives  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{I}$ .

**Isobutenyl alcohol**  $\text{CH}_3\text{CMe}(\text{CH}_2)\text{OH}$ . (113°). S.G.  $\frac{1}{4}$  0.8695. Formed by boiling isobutenyl chloride with very dilute  $\text{K}_2\text{CO}_3$  (Scheschukoff, J. R. 16, 499). Dilute  $\text{H}_2\text{SO}_4$  changes it to isobutyric aldehyde.  $\text{HI}$  forms tert-butyl iodide.

**Ethyl ether**  $\text{CH}_3\text{CMe}(\text{CH}_2)\text{OEt}$  (78°–85°). From isobutenyl chloride and  $\text{KOEt}$ .

**Sec-isobutenyl alcohol**  $\text{CMe}_2\text{CH}_2\text{OH}$ .  
**Methyl ether**  $\text{CMe}_2\text{CH}_2\text{OMe}$ .  
**Methyl isocrotyl oxide**. (70°–74°). From bromo-isobutylene and  $\text{NaOMe}$  at 140°. Dilute  $\text{H}_2\text{SO}_4$  at 140° gives  $\text{HOMe}$  and isobutyric aldehyde (Elte-koff, B. 10, 705; J. R. 9, 163).

**Ethyl ether**  $\text{CMe}_2\text{CH}_2\text{OEt}$ . (93°). Similarly prepared (E.; S.; Butlerow, Z. 1870, 521).

**BUTENYL-TRI-AMINE**  $\text{OH}(\text{CH}_2\text{NH}_2)_3$ . (above 150°). From the nitrile of methane tri-carboxylic acid  $\text{CH}(\text{CN})_3$ , tin, and  $\text{HCl}$ .— $\text{B}_2\text{H}_3\text{PtCl}_6$  (Fairlie, C. J. 16, 362).

**BUTENYL-BENZENE** v. PHENYL-BUTYLENE.  
**BUTENYL CHLORIDE** v. CHLORO-BUTYLENE.

(a) **BUTENYL-CUPRENE**  $\text{C}_4\text{H}_7\text{PrC}_4\text{H}_7$ . Iso-propyl-butenyl-benzene. (213°). S.G.  $\frac{1}{4}$  0.875. Obtained from bromo-cinnyl-valeric acid  $\text{C}_6\text{H}_5\text{Pr}(\text{CH}_2)_2\text{CBrEt}(\text{CH}_2)_2\text{H}$  and  $\text{Na}_2\text{CO}_3\text{Aq}$  (Perkin, C. J. 32, 662). For as a dibromide (77°).

(b) **Butenyl-cuprene**  $\text{H}_2\text{PrC}_4\text{H}_7$ . (235°). S.G.  $\frac{1}{4}$  0.889. Cinnamic aldehyde (10 g.) sodio isobutyrate (5 g.) and isobutyric anhydride (15 g.) are heated together. The oily product is distilled with water and then over solid  $\text{KOH}$  and  $\text{Na}$  (Perkin, C. J. 35, 141). It forms a liquid dibromide.

**BUTENYL-GLYCERIN** v. TRI-OXY-BUTANE.  
**DI-BUTENYL-KETONE** v. DI-ALLYL-ACETONE (p. 131).

**o-BUTENYL-PHENOL**.

**Methyl ether**  
 $[2:1] \text{MeO}(\text{C}_6\text{H}_4)_2\text{CH}(\text{CH}_2)_2\text{CH}_3$ . (233°). S.G.  $\frac{1}{4}$  0.917;  $\frac{25}{20}$  0.940. From the methyl derivative of oxy-phenyl-angelic acid by successive treatment with  $\text{HI}$  and  $\text{Na}_2\text{CO}_3\text{Aq}$  (Perkin, C. J. 33, 213). Oil. Combines with bromine. Forms a red solid with  $\text{H}_2\text{SO}_4$ .

**p-Butenyl-phenol**. **Methyl ether**  
 $[4:1] \text{MeO}(\text{C}_6\text{H}_4)_2\text{C}_4\text{H}_9$ . (17°). (213°). S.G.  $\frac{20}{20}$  0.973. Prepared like the preceding (Perkin, C. J. 32, 671).

**o-Iso-butenyl-phenol**  $\text{C}_{10}\text{H}_{12}\text{O}$  i.e.  $\text{C}_6\text{H}_4\text{C}_4\text{H}_7\text{OH}$ . (223°–225°). S.G.  $\frac{150}{150}$  1.017. Salicylic aldehyde (30 g.) sodio isobutyrate (22 g.) and isobutyric anhydride (15 g.) are heated together for 4 hours. Water is added to the product, and the oily butenyl-phenyl isobutyrate saponified by alcoholic  $\text{KOH}$ . The alcohol is boiled off, dilute  $\text{HCl}$  is added and the oil which separates is distilled (Perkin, C. J. 35, 142). **Properties**.—Oil, with smoky and cedar-like odour. Sol. potash but insol.  $\text{NH}_3$ . With salicylic aldehyde and conc.  $\text{H}_2\text{SO}_4$  it forms a purple solution.

**p-Iso-butenyl-phenol**  $\text{C}_{10}\text{H}_{12}\text{O}$  i.e.  $\text{C}_6\text{H}_4\text{C}_4\text{H}_7\text{OH}$ . (230°–235°). From p-oxy-benzoic aldehyde, sodio isobutyrate and butyric anhydride. Yield small (Perkin, C. J. 35, 145). An oil which solidifies in a freezing mixture.

**Methyl ether**  $\text{C}_6\text{H}_4\text{C}_4\text{H}_7\text{OMe}$ . (9°). (237°). From anisic aldehyde (20 g.), sodio isobutyrate (15 g.) and isobutyric anhydride (30 g.) by boiling at 180°. The product is distilled with steam and the oil is recovered over  $\text{K}_2\text{CO}_3$ . Cooled by ice and  $\text{HCl}$  it solidifies. On oxidation it yields anisic and acetic acid.

**o-BUTENYL-STYRENE**  $\text{C}_8\text{H}_7\text{CH}(\text{CH}_2)_2\text{C}_6\text{H}_5$ . (215°–248°). **Phenyl heximene**. Cinnamic aldehyde (10 g.), sodium isobutyrate (15 g.) and isobutyric anhydride (10 g.) are heated together for two hours.  $\text{CO}_2$  comes off, and the residue is distilled with steam, washed with  $\text{NH}_3$ , dried and rectified over  $\text{Na}$  (Perkin, C. J. 35, 141).

**Properties**.—Lighter than water. Rapidly oxidises in air, becoming a resin. It combines with bromine.

**ISO-BUTENYL-TOLYLENE-o-DIAMINE**

$\text{C}_{11}\text{H}_{17}\text{N}_2$  i.e.  $\text{C}_6\text{H}_4\text{CH}(\text{NH}_2)_2\text{C}_4\text{H}_7$ . (158°).

Formed, together with a small quantity of tolu-  
butyraldehyde  $C_6H_5 \cdot N \cdot CH \cdot C_2H_5$ , by shaking  
a cold acetic acid solution of tolylene-o-  
diamine (1 mol.) with an aqueous or alcoholic  
solution of butyric aldehyde (2 mols.). Small  
colourless needles. V. sol. alcohol and ether,  
sl. sol. water. Very bitter taste (Hinsberg, *B.*  
20, 1589).

**BUTINENE**  $C_8H_{16}$ . *Pe.*  $CH_3 \cdot CH \cdot CH \cdot CH_3$ .  
*Erythrene.* *Vinyl-ethylene.* *Pyrrylene.*  
Occurs in the liquid got by compressing coal-gas  
(Caventou, *B.* 6, 70; Grimaud a. Cloez, *C. R.*  
104, 118). Formed also (?) by passing fusel oil  
through a red-hot tube (Caventou, *A.* 127, 93).  
Obtained by boiling erythrite with conc. formic  
acid (5 pts.) (Henninger, *B.* 6, 70); and by  
the action of KOH on di-methyl-pyrrolidine  
methyl-iodide (Ciamician a. Magagnoli, *B.* 19,  
569). A gas. It forms a tetrabromide [119].  
Pyrrylene and the butinene from erythrite  
form also a second tetrabromide [40] so that  
they are probably mixtures of two butinenes.

**Butinene**  $CH_3 \cdot CH_2 \cdot C \cdot CH_3$ . *Ethyl-acetylene*  
*Crotonylene.* (18°). From methyl ethyl ketone  
by successive treatment with alcoholic KOH and  
 $PCl_5$  (Braylants, *B.* 8, 412). Gives a white pp. in  
ammoniacal  $AgNO_3$  and a yellow pp. in am-  
moniacal cuprous chloride. Mercuric chloride  
solution gives a pp. of  $(C_4H_6)_2(HgOH)_2Cl_2$ ,  
(Kutscheroff, *B.* 17, 24), whence  $HCl$  produces  
methyl ethyl ketone. The same butinene  
appears to be formed when a mixture of  
acetylene and ethylene is passed through a  
red hot tube. It forms a tetrabromide [113]  
(Berthelot, *A. Ch.* [4] 9, 406; Prunier, *Bl.*  
20, 72; *A. Ch.* [5] 17, 17; *C. R.* 76, 1410).

**Butinene**  $CH_3 \cdot C \cdot C \cdot CH_3$  (?). *Crotonylene.*  
(18°). From crude butylene bromide and alco-  
holic KOH (Caventou, *A.* 127, 347). From  $\alpha$ -  
di-bromo-butane and alcoholic KOH (Almedin-  
gen, *J. R.* 13, 392). Also formed by distilling  
barium acetate with S (Pankueh, *J. pr.* [2]  
6, 110).  $H_2SO_4$  (3 mols.) diluted with water  
(1 mol.) converts it into hexa-methyl-benzene.

**Butinene**  $C_4H_6$ . *Caoutchou.* [-10°]. (15°).  
S.G. = 0.65. Formed by the dry distillation of  
caoutchou (*q. v.*) (Bouchardat, *A.* 27, 33).

**BUTINENE GLYCOL** *v.* DI-OXY-BUTYLENE.

**BUTONENE-AMIDO-PHENYL MERCAP-**

**TAN**  $C_{10}H_{12}N_2S_2$  *i.e.*

$C_6H_5 \cdot N \cdot \begin{array}{c} \diagup \\ \diagdown \end{array} \begin{array}{c} C \cdot CH_2 \cdot C \cdot N \\ \diagdown \\ \diagup \end{array} \cdot C_6H_5$ . [137°].

From amido-phenyl-o-mercaptan and succin-  
amide (Hofmann, *B.* 13, 1231). Needles (from  
alcohol).— $B^*HAuCl$ .

**BUTYL DERIVATIVES** of hydroxylic com-  
pounds are described under the compounds of  
which they are the ethers.

**DI-BUTYL** *v.* OCTANE.

**BUTYL ACETATE**  $C_4H_9 \cdot O_2$  *i.e.*  $C_4H_9 \cdot OAc$ .  
(124.5°). S.G. = 0.9016. C.E. (0°-10°) 00113.  
S.V. 150.6 (Gartenmeister, *A.* 233, 259). From  
butyl iodide and  $AgOAc$  (Lieben a. Rossi, *A.*  
158, 170; Linnemann, *A.* 161, 193; Pribram a.  
Handl, *M.* 2, 693).

**Isobutyl acetate**  $(CH_3)_2CH \cdot CH_2 \cdot OAc$ . V.D.  
4.073 (calc. 4.017). (116.8°) (Elsasser, *A.*  
218, 326); (117° cor.) (Perkin, *C. J.* 45, 495;  
(112.8°) (R. Schiff, *A.* 220, 109). S.G. = 0.8921  
(*E.*);  $\frac{1}{4}$  0.8774;  $\frac{3}{4}$  0.8688 (P.). C.E. (0°-10°)

001137 (*E.*). M.M. 6.623 at 10°. S.V. 150-10  
(*E.*); 152.5 (*S.*). Formed from isobutyl iodide  
and  $AgOAc$ , or by distilling potassium isobutyl  
sulphate with  $KOAc$  (Wurtz, *A.* 90, 121).

**Sec-Butyl acetate**  $CH_3 \cdot CH_2 \cdot CH(OAc) \cdot CH_3$ .  
(112°). S.G. = 0.892. From sec-butyl iodide and  
 $AgOAc$  (De Luynes, *J.* 1864, 501; Lieben, *A.*  
150, 112).

**Tertiary Butyl acetate**  $(CH_3)_3C \cdot OAc$ . (93°-  
96°). From the iodide and  $AgOAc$ . Readily  
saponified by baryta-water (Butlerow, *A.* 144, 7).

**ISO-BUTYL-ACETIC ACID** *v.* HEXANOIC ACID.

**ISOBUTYL-ACETO-ACETIC ETHER** *v.* p. 24.

**BUTYL-ACRIDINE**  $C_{17}H_{15}N$  *i.e.*

$C_6H_5 \cdot \begin{array}{c} \diagup \\ \diagdown \end{array} \begin{array}{c} C(C_2H_5) \\ \diagdown \\ \diagup \end{array} \cdot C_6H_5$ . From valeric acid (30 g.), di-  
phenylamine (30 g.) and  $ZnCl_2$  (50 g.) heated  
gradually for 20 hours up to 220° (Berthsen a.  
J. Traube, *A.* 224, 41; *B.* 17, 1508).

**Salts.**— $B^*HCl$  [191°]: yellow columns, *v.*  
sol. water or alcohol, very dilute solutions show  
blue fluorescence. Insol. ether.— $B^*HNO_3$  [139°].—  
 $B^*H_2CrO_4$  [*c.* 100°].

**Dihydride**  $C_{13}H_{13}N(C_2H_5)_2$ . [98°-100°]. Got  
by reducing the hydrochloride with zinc-dust.  
White plates (from alcohol).

**BUTYLACTIC ACID** *v.* OXY-BUTYRIC ACID.

**BUTYLAL** *v.* BUTYRIC ALDEHYDE.

**BUTYL ALCOHOL**  $C_4H_9 \cdot O$ . Mol. w. 74. The  
four butyl alcohols indicated by theory are  
known.

**n-Butyl-alcohol**  $CH_3 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot OH$ . (117°  
cor.). S.G. = 0.8233 (Zander, *A.* 221, 79);  $\frac{1}{4}$  0.8096  
(Brühl, *A.* 203, 16). S. 8.3. C.E. (0°-10°) 00087  
(Z.).  $\mu_p$  1.4010. S.V. 101.6 (Schiff, *A.* 220,  
101).  $R_{\infty}$  35.45 (B.). **Critical point** 287°  
(Paulowsky, *B.* 16, 2634).

**Occurrence.**—In the heavy oils from brandy.  
It is completely absent from the products of the  
fermentation of sugar with elliptical yeast  
(Clandon a. Morin, *C. R.* 101, 1187).

**Formation.**—1. From butyl chloride, butyric  
acid and sodium-amalgam (Saytzeff, *J. pr.* [2]  
3, 76).—2. By the fermentation of glycerin by  
a *Schizomyces* or by certain *Bacteria* in pre-  
sence of  $CaCO_3$  and ammonium tartrate; *n*-  
butyric acid and a little alcohol are formed at  
the same time (Fitz, *B.* 9, 1348; Vigna, *B.* 16,  
1438).—3. A product of the reduction of butenyl  
alcohol (Lieben a. Zeisel, *M.* 1, 825).

**Preparation.**—From butyric aldehyde,  
water, and sodium-amalgam (Lieben a. Rossi,  
*C. R.* 68, 1561; 78, 1561; *A.* 151, 121; 158, 137;  
165, 145; *C. J.* 24, 516; Linnemann, *A.* 161, 179).

**Properties.**—Liquid. Separated by  $CaCl_2$   
from aqueous solution. On oxidation it produces  
butyric acid. Fused  $ZnCl_2$  forms the two *n*-  
butylenes (Le Bel a. Greene, *C. R.* 89, 413).

**Combination.**— $(C_4H_9O)_2CaCl_2$  (Heindl, *M.*  
2, 200).

**Iso-butyl alcohol**  $(CH_3)_2CH \cdot CH_2 \cdot OH$ . (106.6°-  
106.8°) at 763.2 mm. (R. Schiff, *A.* 220, 102)  
(108°) (Linnemann, *A.* 160, 238). S.G. = 0.8062  
(Brühl);  $\frac{1}{4}$  0.8069;  $\frac{3}{4}$  0.8009 (P.). S. 9.5 at 18°.  
S.V. 101.63. H.F. p. 71.150. H.F. *v.* 68,580  
(Th.).  $\mu_p$  1.4007.  $R_{\infty}$  35.41. M.M. 4.936 at  
17.7°.

**Occurrence.**—In fusel oil from beet or pota-  
toes and other sources (Wurtz, *A. Ch.* [3] 42,  
129; *A.* 85, 197; 93, 107; *C. R.* 85, 810).

yl angelate and isobutyrate occur in Roman oil of chamomile (Köbig, A. 195, 96).

**Formation.**—1. Isobutylene combines with  $\text{ClOH}$  forming  $(\text{CH}_3)_2\text{CCl.CH}_2\text{OH}$ , which is reduced by sodium amalgam and water (Butlerow, A. 144, 24).—2. Isobutyl alcohol is produced by the action of *Bacillus butylicus* upon sugar, glycerin, &c., even in presence of 8 p.c. alcohol (Ordonneau, U. R. 102, 219; Claudon a. Morin, C. R. 104, 1187).

**Properties.**—Liquid; smelling like fusel oil; separated from its aqueous solution by  $\text{CaCl}_2$ . The rate of etherification has been studied by Menshutkin (A. Ch. [5] 23, 14).

**Reactions.**—1.  $\text{CrO}_3$  produces isobutyric, carbonic acids, and acetone (Krämer, B. 7, 252; Schmidt, B. 7, 1361).—2. Distilled over zinc dust splits up into isobutylene and  $\text{H}_2\text{O}$  (Jahn, B. 13, 989).—3. Dropped upon fused  $\text{ZnCl}_2$  it forms isobutylene and  $\text{CH}_3\text{CH}:\text{CH}.\text{CH}_3$  (Le Bel a. Greene, Am. 2, 23).—4. Heated with ammoniacal  $\text{ZnCl}_2$  at  $260^\circ\text{--}280^\circ$  it yields a mixture of mono-, di- and tri-isobutylamine (the latter in smaller quantity), the yield of mixed bases amounting to 50 to 70 p.c. of the alcohol used (Merz a. Gasiorowski, B. 17, 623).

**Combinations.**— $(\text{C}_4\text{H}_9\text{O})_2\text{CaCl}_2$  (Heindl, M. 2, 208).

**Metallic derivatives.**— $\text{KOC}_4\text{H}_9$ .— $\text{NaOC}_4\text{H}_9$  ( $\text{C}_4\text{H}_9\text{O}$ )<sub>3</sub> (De Forerand, C. R. 104, 169).— $\text{Al}(\text{OC}_4\text{H}_9)_3$  [ $140^\circ$ ]. S.G.  $\pm 0.825$  (Gladstone a. Tribe, C. J. 39, 6). From Al (1 g.), iodine (2 g.) and isobutyl alcohol 40 c.c. at  $100^\circ$ . The yield is good (16 g.). Once fused it remains long fluid at  $70^\circ$ .

**Secondary butyl alcohol**  
 $\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)\text{H.OH}$ . Methyl-*isobutyl*-carbinol. Butylene hydrate. ( $99^\circ$ ) at 740 mm. S.G.  $\pm 0.827$  (Lieben, A. 150, 114).

**Formation.**—1. From *n*-butylamine by nitrous acid; at the same time some *n*-butyl alcohol is also formed (Linnemann a. Zotta, A. 162, 3; Meyer, B. 10, 130).—2. By treating the compound of  $\text{HClO}$  with isobutylene,  $\text{CH}_3\text{CHCl.CH}(\text{OH})\text{CH}_3$ , with sodium amalgam (Lieben, A. 151, 121).—3. By the action of zinc ethide on glycolic iodhydrin (Butlerow a. Ossokin, A. 145, 263).—4. Symmetrical dichloro-diethyl oxide,  $(\text{CH}_3\text{CHCl})_2\text{O}$  is converted by  $\text{ZnEt}_2$  into  $(\text{CH}_3\text{CHEt})_2\text{O}$ , a butyl ether which, on treatment with  $\text{HI}$  at  $130^\circ$  gives secondary butyl iodide (Lieben, A. 141, 236; Kessel, A. 175, 41).—5. Zinc ethide forms a crystalline compound with aldehyde,  $\text{CH}_3\text{CHEt}(\text{OZnEt})$ , which is decomposed by water into secondary butyl alcohol, ethane, and  $\text{Zn}(\text{OH})_2$  (Wagner, J. R. 8, 37; A. 181, 261).—6. From formic ether by treating with a mixture of  $\text{ZnEt}_2$  and  $\text{ZnMe}_2$  and decomposing the product with water (Kanonnikoff a. Saytzeff, A. 175, 374).

**Preparation.**—Secondary butyl iodide (*q.v.*) is treated with silver acetate and the product saponified by potash (De Luynes, A. 128, 330; 182, 274).

**Properties.**—Liquid with strong odour, ppd. from aqueous solution by  $\text{K}_2\text{CO}_3$ .

**Reactions.**—1. Oxidises to methyl-ethyl-ketone and acetic acid (Saytzeff, Z. 6, 327).—2. The pure alcohol is unaltered when heated at  $240^\circ\text{--}250^\circ$  during 8 to 16 hours in a sealed tube,

Vol. I.

but the presence of a trace of  $\text{HCl}$ ,  $\text{HBr}$ , or especially  $\text{HI}$ , is sufficient to split it up, forming pseudobutylene. The reaction commences at  $220^\circ$  and is complete in 5 or 6 hours (Bougaleff a. Wolkoff, Bl. [2] 45, 9).

**Tertiary butyl alcohol**  $(\text{CH}_3)_3\text{C.OH}$ . Trimethyl-carbinol. ( $25^\circ$  (83° cor.). S.G.  $\pm 0.779$  (Linnemann);  $29^\circ 7'$  (Butlerow);  $29^\circ 786$ ;  $29^\circ 780$  (Brühl);  $1^\circ 7836$ ;  $3^\circ 7761$  (Perkin). M.M. 5.122 at  $24.3^\circ$ .  $n_D^{20}$  1.3921.  $n_D^{25}$  1.3853. Critical point  $235^\circ$  (Pawlewski, B. 16, 2634).

**Formation.**—1. Zinc methide (2 mols.) and acetyl chloride (3 mol.) mixed at  $0^\circ$ , form, after some time, a crystalline compound,  $\text{CH}_3\text{CMe}(\text{OZnMe})_2$ , which is decomposed by water into tertiary butyl alcohol,  $\text{Zn}(\text{OH})_2$  and  $\text{CH}_4$  (Butlerow, A. 141, 1; Wagner a. Saytzeff, A. 175, 361; Pawloff, A. 188, 118).—2. Together with isobutyl alcohol by treating isobutyl iodide with acetic acid and  $\text{Ag}_2\text{O}$  (Linnemann, A. 162, 12; Butlerow, A. 168, 143).—3. From isobutylamine and  $\text{HNO}_3$ .—4. From isobutyl cyanate and  $\text{KOH}$  (Linnemann, A. 162, 12).—5. From tertiary butyl iodide (*q.v.*) and water, even in the cold (Dobbin, C. J. 37, 238).—6. A mixture of *iso*- and *tert*-butyl chlorides is got by heating isobutyl alcohol with  $\text{HCl}$ ; when heated with water (6 vols.) at  $100^\circ$  the chloride of *tert*-butyl alcohol is the only one converted into its alcohol (Freund, J. pr. [2] 12, 25).

**Preparation.**—Liquid isobutylene is sealed up with twice its volume of a mixture of equal parts of water and sulphuric acid, and the contents are left till homogeneous and then distilled (Butlerow, Z. [2] 237; A. 180, 216).

**Properties.**—Tricentric prisms. Forms a hydrate  $(\text{C}_4\text{H}_9\text{O})_2\text{H}_2\text{O}$  which boils at  $80^\circ$  (Butlerow).

**Reactions.**—1.  $\text{CrO}_3$  mixture gives acetone together with acetic, carbonic and a little isobutyric acid (Butlerow, Z. 1871, 485).—2. Heating with anhydrous  $\text{H}_2\text{C}_2\text{O}_4$  produces butylene (Cahours a. Demareny, C. R. 86, 931).—3. When taken internally it is excreted in the urine as butyl-glycuronic acid  $\text{C}_4\text{H}_9\text{H}_5\text{O}$  (Thierfelder a. Mering, H. 9, 514) which is decomposed by boiling dilute  $\text{HCl}$  into *tert*-butyl alcohol and glycuronic acid.

**DI-ISOBUTYL ALDEHYDATE** *v.* p. 105.

**ISO-BUTYL ALDEHYDE** *v.* ISOBUTYRIC ALDEHYDE.

**ISO-BUTYL-ALDOXIM** *v.* ISOBUTYRIC ALDEHYDE.

**ISO-BUTYL-AMIDO-ISO-BUTYL-BENZENE**  $\text{C}_4\text{H}_9\text{NH.C}_6\text{H}_4\text{C}_4\text{H}_9$ . ( $260^\circ\text{--}270^\circ$ ). From aniline hydrochloride (10 g.) and *iso*-butyl alcohol (13 g.) at  $230^\circ$  (Studer, A. 211, 240; B. 14, 1473). Oil. Does not give the carbamine reaction.

**Nitroso-derivative** S.G.  $\pm 0.991$ . Solidifies on keeping.

**Acetyl-derivative**  $\bullet$  [ $74^\circ$ ]. (above  $800^\circ$ ). Nodules (from benzoline).

**BUTYL-AMIDO-TOLUENE** *v.* METHYL-BUTYL-PHENYL-AMINE.

***n*-BUTYLAMINE**  $\text{C}_4\text{H}_9\text{NH}_2$  *i.e.*  $\text{Pr.CH}_2\text{NH}_2$ . Mol. w. 73. ( $76^\circ$ ). S.G.  $\pm 0.755$ ,  $25^\circ 733$ .

**Formation.**—1. From butyl cyanate and  $\text{KOH}$  (Lieben a. Rossi, A. 158, 172; Meyer, B. 10, 131).—2. From butyronitrile by reduction

T T

(Linnemann a. Zotta, *M.* 162, 8).—3. From nitrobutane, Sn and HCl (Züblin, *B.* 10, 2083).

**Properties.**—Miscible with water; dissolves freshly ppd. Cu(OH)<sub>2</sub> and Ag<sub>2</sub>O. Reduces alkaline solutions of copper, silver, and mercury. Nitrous acid converts it into *sec*-butyl alcohol.—Platino-chloride (B<sup>2</sup>HCl)<sub>2</sub>PtCl<sub>4</sub>: yellow crystalline plates, m. sol. in cold water.

**Primary isobutyl-amine** Pr.C<sub>4</sub>H<sub>9</sub>NH<sub>2</sub>. (68°) (R. Schiff, *B.* 19, 565). S.G. 0.736. S.V. 106.16 (S.). H.F. p. 38,460. I.P. v. 35,560 (Th.).

**Formation.**—1. By distilling potassium isobutyl sulphate with potassium cyanate and treating the product with KOH (Kurtz, *A.* 93, 124; Linnemann, *A.* 162, 23).—2. By heating isobutyl bromide with alcoholic NH<sub>3</sub> and separating the mono-, di-, and tri-butylamines by oxalic ether (Reimer, *B.* 3, 756; Hughes a. Römer, *B.* 7, 511; Malbot, *C. R.* 104, 63, 228). On heating isobutyl chloride with ammonia (molecular proportions) in isobutyl alcoholic solution or in aqueous solution very nearly similar results are obtained; namely one part of mono-butylamine, four of di-, and five parts of tri-butylamines (M.).—3. Formed, together with di- and tri-isobutylamine, by heating isobutyl-alcohol with ammoniacal ZnCl<sub>2</sub> at 260°–280°; the yield of mixed bases amounts to 50–70 p.c. of the alcohol used (Merz a. Gasiorowski, *B.* 17, 623). 4. By reducing nitro-isobutane (Demole, *A.* 175, 142).—5. A mixture of equal mols. of valeramide (ordinary) and bromine is run into an excess of a 10 p.c. solution of KOH at 60°; the yield is 90 p.c. (Hofmann, *B.* 15, 769).

**Salts.**—B<sup>2</sup>HCl. [160°]. S. 133 at 15°.—(B<sup>2</sup>HCl)<sub>2</sub>PtCl<sub>4</sub>: microscopical rhombic tablets.—B<sup>2</sup>HAuCl<sub>4</sub>.—Sulphate: cauliflower-like groups of needles, not deliquescent.

**Secondary butyl-amine** CH<sub>3</sub>.CH<sub>2</sub>.CH(NH<sub>2</sub>).CH<sub>3</sub>. (63°). From dilute H<sub>2</sub>SO<sub>4</sub> and *sec*-butyl thio-carbimide (from volatile oil of scurvy-grass) (Röman, *B.* 7, 1289). Also from the iodide or cyanate (Hofmann, *B.* 7, 513).—B<sup>2</sup>H<sub>2</sub>PtCl<sub>6</sub>.

**Tertiary butyl-amine** Me.CNH<sub>2</sub>. (46° cor.). S.G. 0.7155;  $\lambda_D^{20}$  7001. C.B. (0°–7.8°) 0.014. Formed together with isobutylamine by the successive action of silver cyanate and aqueous KOH on isobutyl iodide. Colourless ammoniacal liquid, attacks indiarubber and cork. Miscible with water, but separated by K<sub>2</sub>CO<sub>3</sub> or KOH from its solution (Brauner, *A.* 192, 72; cf. Linnemann, *A.* 162, 19; Hofmann, *B.* 7, 513).

**Salts.**—B<sup>2</sup>HCl melts at [–70°–280°] and boils soon after. On solidifying it increases greatly in bulk.—(B<sup>2</sup>HCl)<sub>2</sub>PtCl<sub>4</sub>. Large monoclinic prisms (from alcohol).—B<sup>2</sup>HL.—B<sup>2</sup>HNO<sub>3</sub>. **Sulphate**: six-sided prisms, not deliquescent.

**Di-*n*-butyl-amine** (Pr.C<sub>4</sub>H<sub>9</sub>)<sub>2</sub>NH. (160°). Formed, together with *n*-butylamine, by treating butyl cyanate with KOH (Lieben a. Rossi, *A.* 158, 175). Converted by nitrous acid into primary and secondary *n*-butyl alcohols and *n*-butylene (Meyer, *B.* 10, 130).—B<sup>2</sup>H<sub>2</sub>PtCl<sub>6</sub>. **Nitroso-derivative** (C<sub>4</sub>H<sub>9</sub>)<sub>2</sub>N.NO. (236° cor.).

**Di-iso-butyl-amine** (Pr.C<sub>4</sub>H<sub>9</sub>)<sub>2</sub>NH. (137°). Formed, together with mono- and tri-iso-butylamine, by heating iso-butyl alcohol with ammoniacal ZnCl<sub>2</sub> at 260°–280°. The secondary amine is isolated from the mixture of bases (which amounts to 50–70 p.c. of the alcohol

used) by means of its nitrosamine (Merz a. Gasiorowski, *B.* 17, 623). Prepared by heating iso-butyl iodide or bromide with alcoholic NH<sub>3</sub> to 150° (Ladenburg, *B.* 12, 948). Butyl iodide (1 mol.) in the cold acts upon di-isobutylamine (1 mol.) forming di-isobutylamine hydrochloride and free tri-iso-butylamine (M.).

**Salts.**—B<sup>2</sup>HCl: plates or scales. S. 62.5 at 15°; S. (ether) 0.7 at 15°; S. (alcohol) 0.6 at 14° (Malbot, *C. R.* 104, 366).—B<sup>2</sup>H<sub>2</sub>PtCl<sub>6</sub>.—B<sup>2</sup>HClAuCl<sub>4</sub>. Yellow tables, sparingly soluble in cold water.

**Nitroso-derivative** N(NO)(C<sub>4</sub>H<sub>9</sub>)<sub>2</sub>. [0°]. (213°–216°). Oil. Prepared by the action of KNO<sub>2</sub> on a solution of di-isobutylamine hydrochloride.

**Tertiary di-butyl-amine** (C<sub>4</sub>H<sub>9</sub>)<sub>3</sub>NH *i.e.* (CMe)<sub>3</sub>NH. From tertiary butyl iodide and tertiary butylamine at 50°. But above 70° isobutylene is given off: C<sub>4</sub>H<sub>9</sub>NH<sub>2</sub> + C<sub>4</sub>H<sub>9</sub>I = C<sub>4</sub>H<sub>8</sub> + C<sub>4</sub>H<sub>9</sub>NH<sub>2</sub>III (Rudnow, *Bl.* [2] 33, 299).

**Salt.**—B<sup>2</sup>HL. Very soluble in water and alcohol. Converted by potash, or even boiling water, into tertiary butylamine.

**Tri-*n*-butyl-amine** (C<sub>4</sub>H<sub>9</sub>)<sub>3</sub>N. Mol. w. 185. (e. 213° cor.). S.G. 0.791;  $\lambda_D^{20}$  778. From *n*-butyl iodide and NH<sub>3</sub> (Lieben a. Rossi, *A.* 165, 115).—B<sup>2</sup>H<sub>2</sub>PtCl<sub>6</sub>.

***n*-Butylo-iodide** (C<sub>4</sub>H<sub>9</sub>)<sub>2</sub>NI: plates (Lieben a. Rossi, *A.* 165, 113).

**Tri-isobutyl-amine** (Pr.C<sub>4</sub>H<sub>9</sub>)<sub>3</sub>N. (185°). S.G. 0.785 (Sachtleben, *B.* 11, 733). Formed, together with mono- and di-iso-butylamine, by heating isobutyl alcohol with ammoniacal ZnCl<sub>2</sub> at 260°–280°. The tertiary amine is isolated from the mixture of bases (yield 50–70 p.c. of the alcohol) by means of its sparingly soluble ferrocyanide (Merz a. Gasiorowski, *B.* 17, 623). Also from di-iso-butylamine and isobutyl bromide. Also from isobutyl iodide (1 mol.) and NH<sub>3</sub>Aq (1 mol.) at 160° (Malbot, *C. R.* 105, 575). Does not mix with water. With isobutyl bromide it gives off butylene and forms tri-isobutylamine hydrobromide (Reimer, *B.* 3, 757). Isobutyl iodide (1 mol.) at 180° forms hydriodides of di- and tri-isobutylamine and butylene (M.). Isobutyl chloride (1 mol.) at 170° gives pure di-isobutylamine hydrochloride and butylene.

**Salts.**—B<sup>2</sup>HCl, B<sup>2</sup>HNO<sub>3</sub> and B<sup>2</sup>H<sub>2</sub>SO<sub>4</sub> are extremely soluble.—(B<sup>2</sup>HCl)<sub>2</sub>PtCl<sub>4</sub>: orange plates, sol. hot water.—B<sup>2</sup>HClAuCl<sub>4</sub>: amorphous, insol. water.

#### **Tert-BUTYL-tert-AMYL-AMINE**

(C<sub>4</sub>H<sub>9</sub>)(C<sub>5</sub>H<sub>11</sub>)NH. The iodide of this base is formed by the slow action of tertiary amyl iodide on tertiary butylamine in the cold. It is very unstable, being decomposed by solution in water (?) (Rudnow, *Bl.* [2] 33, 297).

***n*-BUTYL-ANILINE** C<sub>10</sub>H<sub>13</sub>N *i.e.* C<sub>6</sub>H<sub>5</sub>.NH.C<sub>4</sub>H<sub>9</sub>. (235° at 720°). Colourless oily fluid. Easily volatile with steam.

**Salts.**—B<sup>2</sup>HCl: very soluble white needles.—B<sup>2</sup>HINO<sub>3</sub>: easily soluble.—B<sup>2</sup>H<sub>2</sub>SO<sub>4</sub>: easily soluble fine white needles.

**Acetyl derivative** C<sub>6</sub>H<sub>5</sub>.N(C<sub>4</sub>H<sub>9</sub>)Ac: (274°) at 718 mm., colourless fluid.

**Nitrosamine** C<sub>6</sub>H<sub>5</sub>.N(C<sub>4</sub>H<sub>9</sub>)NO: yellow fluid; easily soluble in alcohol and ether, insoluble in water (Kahn, *B.* 18, 3365).

**Isobutyl-aniline**  $\text{Pr.C}_4\text{H}_9\text{NHPH}$ . (242°) (G.); (226°) (N.). S.G. 1.1926 (G.). From isobutyl bromide and aniline (Gianetti, *G.* 12, 268).— $\text{B'HCl}$ — $\text{B'HBBr}$ — $\text{B'HI}$ .

**Acetyl derivative** (267°) (Nölting, *J.* 1883, 703).

**p-Nitroso-derivative**

[41]  $\text{C}_6\text{H}_4(\text{NO}).\text{NHCH}_2\text{Pr}$  or  $\text{C}_6\text{H}_4\text{N}(\text{CH}_2\text{Pr})_2$

[94°]. From isobutyl-aniline,  $\text{HCl}$ , and  $\text{NaNO}_2$  (Wacker, *A.* 243, 297). Steel-blue crystals, v. sol. alcohol, sl. sol. water. *Reactions*.—1. *Reduction* gives isobutyl-phenylene diamine.—2. The chloro-derivative with aqueous  $\text{NaOH}$  gives iso-butyl-amine and  $p$ -nitroso-phenol.—3.  $\text{HCl}$  and  $\text{NaNO}_2$  give a nitrosamine  $\text{C}_6\text{H}_4(\text{NO}).\text{N}(\text{NO}).\text{CH}_2\text{Pr}$  crystallising in bright green plates, v. sol. alcohol and ether, insol. water.

**Di-isobutyl-aniline**  $(\text{Pr.C}_4\text{H}_9)_2\text{NPH}$ . (c. 218°). From aniline and isobutyl bromide (Studer, *A.* 211, 235).

**DI-BUTYL-ANILINE-AZYLINE** v. *Di-butyl-amido-benzene-azo-di-butyl-aniline*.

**BUTYL-ANISOL** v. *Methyl ether of BUTYL-PHENOL*.

**ISO-BUTYL-ANTHRACENE**  $\text{C}_{15}\text{H}_{12}$ , i.e.  $\text{C}_6\text{H}_3(\text{CH}(\text{C}_4\text{H}_9))_2$  [57°]. Fluorescent

needles. Prepared by the action of zinc-dust, isobutyl bromide and  $\text{NaOH}$  on anthraquinone (Liebmann a. Tobias, *B.* 14, 802; *A.* 212, 107). The picric acid compound forms long brownish-red needles.

**Di-hydride**  $\text{C}_6\text{H}_3(\text{CH}(\text{C}_4\text{H}_9))_2$  From isobutyl-oxanthranol, III, and  $\text{P}$  (Li.). Oil; oxidised by  $\text{CrO}_3$  in  $\text{HOAc}$  to isobutyl-oxanthranol and finally to anthraquinone.

**BUTYL-ANTHRANOL-DIHYDRIDE**

$\text{C}_6\text{H}_3(\text{CH}(\text{OH})(\text{C}_4\text{H}_9))_2$  [72°]. From anthraquinone, aqueous  $\text{NaOH}$  and zinc-dust, boiled for some time and then iso-butyl bromide added (Liebmann, *A.* 212, 103).

**ISO-BUTYL-ANTHRANIL CHLORIDE**

$\text{C}_6\text{H}_3(\text{CCl}(\text{C}_4\text{H}_9))_2$  [78°]. Tables. Prepared by the action of  $\text{PCl}_5$  on isobutyl-oxanthranol (Liebmann a. Walder, *B.* 14, 463).

**n-BUTYL-BENZENE**  $\text{C}_{10}\text{H}_{14}$ , i.e.  $\text{C}_6\text{H}_5.\text{CH}_2\text{Pr}$ . *Phenyl-butane*. (180°). S.G. 1.862. From  $n$ -propyl bromide, benzyl chloride, and  $\text{Na}$  (Radziszewski, *B.* 9, 260). Also from  $n$ -butyl bromide, bromo-benzene, and  $\text{Na}$  (Balbiano, *B.* 10, 296).

**Bromination**.—By the action of bromine in the dark, or in presence of iodine, the product is probably a mixture of  $o$ - and  $p$ -bromo-butyl-benzene. By the action of bromine in direct sunshine, the substitution takes place in the  $\gamma$ -position of the side-chain giving  $\text{C}_6\text{H}_5.\text{CHBr.C}_2\text{H}_5$ , or  $\text{C}_6\text{H}_5.\text{CBr}_2.\text{C}_2\text{H}_5$ . If the  $\gamma$ -mono-bromo-derivative is further brominated in the dark at 100° the second  $\text{Br}$  atom probably enters the  $\beta$ -position, the product being identical with the butylene-benzene-dibromide [70°] of Radziszewski (Schramm, *B.* 18, 1275).

**ISO-BUTYL-BENZENE**  $\text{C}_6\text{H}_5.\text{CH}_2\text{Pr}$ . (167°). S.G. 1.880 (G.); 1.858 (B.). V.D. 4.72 (G.).

**Formation**.—1. From isobutyl bromide, bromo-benzene and  $\text{Na}$  (Riess, *B.* 8, 779; Wreden a. Znawicz, *B.* 9, 1606).—2. From benzyl chloride, isopropyl iodide, and  $\text{Na}$  (Köhler a. Aronheim, *B.* 8, 541).—3. By the action of 50 g. iso-butyl chloride on 150 g. benzene in presence of about 5 g.  $\text{Al}_2\text{Cl}_3$  (Gossin, *Bl.* [2] 41, 446).—4. By heating benzene with isobutyl alcohol and  $\text{ZnCl}_2$  (Foldschmidt, *B.* 15, 1066).—5. By distilling  $m$ - or  $p$ -isobutyl-benzoic acid with lime (Kelbe a. Pfeiffer, *B.* 19, 1728).

**Properties**.—Colourless liquid;  $\text{CrO}_3$  oxidises it to benzoic acid. Passed over red-hot  $\text{PbO}$  it forms naphthalene.

**Sec-butyl-benzene**  $\text{CH}_3.\text{CH}_2.\text{CH}(\text{C}_2\text{H}_5).\text{C}_6\text{H}_5$ . (171°). S.G. 1.873. From  $\text{C}_6\text{H}_5.\text{CHBr.C}_2\text{H}_5$  and  $\text{ZnEt}_2$  (Radziszewski, *B.* 9, 261).

(a) **n-BUTYL-BENZENE SULPHONIC ACID**  $\text{C}_6\text{H}_4(\text{CH}_2)_4.\text{SO}_3\text{H}$ . Formed by sulphonating  $n$ -butyl-benzene (Balbiano, *G.* 7, 343).— $\text{BaA}'_2$ : small laminae, sl. sol. cold water.— $\text{ZnA}'_2.7\text{aq}$ .— $\text{PbA}'_2.\text{aq}$ .— $\text{MnA}'_2.6\text{aq}$ .

( $\beta$ ) **n-Butyl-benzene sulphonic acid**. Formed at the same time as the preceding (Li.).— $\text{BaA}'_2.2\text{aq}$ : nodules, more soluble than the  $\text{Ba}$  salt of the ( $\alpha$ )-acid.— $\text{PbA}'_2.2\text{aq}$ .

**iso-Butyl-benzene-sulphonic acid**  $\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{SO}_3\text{H}$ . Formed by sulphonation of isobutyl-benzene.  $\text{A}'_2.\text{Ba}2\text{aq}$ : glistening plates.— $\text{A}'\text{Kaq}$ : plates.

**Amide**  $\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{SO}_2.\text{NH}_2$  [137°]; glistening needles (Kelbe a. Pfeiffer, *B.* 19, 1728).

**BUTYL BENZOATE** v. p. 470.

**BUTYL BENZIMIDO-ETHER** v. p. 479.

**m-ISO-BUTYL-BENZOIC ACID**

$\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{CO}_2\text{H}$  [133°]. [127°]. Long stout needles. Formed by oxidation of  $m$ -isobutyl-toluene with dilute  $\text{HNO}_3$ . By further oxidation with dilute  $\text{HNO}_3$  at 170°–200° isophthalic acid is formed. Gives a nitro-derivative [140°].— $\text{AgA}'$ : white pp.

**Amide**  $\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{CONH}_2$  [130°]; hair-fine needles from water (Kelbe a. Pfeiffer, *B.* 19, 1725).

**p-Isobutyl-benzoic acid**  $\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{CO}_2\text{H}$  [134°]. [164°].

**Formation**.—1. By oxidation of  $p$ -isobutyl-toluene with dilute  $\text{HNO}_3$ . By further oxidation with dilute  $\text{HNO}_3$  terephthalic acid is formed (Kelbe a. Pfeiffer, *B.* 19, 1725).—2. By saponification of its nitrile (Pahl, *B.* 17, 1237).

**Properties**.—Monoclinic crystals; gives a nitro-derivative [164°].

**Salts**.— $\text{AgA}'$ : white flocculent pp.— $\text{BaA}'_2.2\text{aq}$ : plates, sol. hot water.— $\text{CaA}'_2.2\text{aq}$ : sl. sol. cold water.

**Amide**  $\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{CONH}_2$  [171°]; long hair-fine needles (from water).

**Methyl ether**  $\text{MeA}'$ : (247°); oil.

**Nitrile**  $\text{C}_6\text{H}_4(\text{C}_4\text{H}_9).\text{CN}$ . (249°) (G. a. M.); (244°) (K.); (238°) (P.). V.D. 5.47 (obs.) (K.); 5.35 (obs.) (P.). Colourless oil. **Formation**.—

1. By distilling the formyl derivative of isobutyl-phenyl-amine with zinc-dust; the yield is about 12 p.c. (Gasirowski a. Merz, *B.* 18, 1009).—2. By heating  $p$ -isobutyl-phenyl-thio-carbimide with copper powder at 200° (Pahl, *B.* 17, 1236).—3. Formed by heating tri-isobutylphenyl-phosphate with dry  $\text{KCN}$  (Kreysler, *B.* 18, 1707).

**ISO-BUTYL-BENZOYL-ACETIC ETHER** v. p. 482.

**ISO-BUTYL BORATE**  $B(OC_4H_9)_2$ . (219°). Formed by heating  $B_2O_3$  with isobutyl alcohol for 8 hours at 170°. Burns with green flame. Insol. water and slowly decomposed by it (Counciler, *J. pr.* [2] 18, 382). Not acted upon by ammonia.

**n-BUTYL BROMIDE**  $C_4H_9Br$  *i.e.*  $CH_3CH_2CH_2CH_2Br$ . (10° cor.). S.G.  $\frac{2}{15}$  1.305;  $\frac{22}{15}$  1.299. From *n*-butyl alcohol, Br, and P (Lieben a. Rossi, A. 158, 161). With Br at 150° it gives  $C_4H_8Br_2$  (168°) (Linnemann, A. 161, 199). With bromine containing iodine at 250° it reacts thus:  $C_4H_9Br + 8Br_2 = 2C_4Br_4 + 9HBr$  (Merz a. Weith, B. 11, 2244).

**Isobutyl bromide**  $Pr.C_4H_9Br$ . (92°) (L.); (91°) at 758 mm. (Schiff, B. 19, 563). S.G.  $\frac{15}{15}$  1.2722;  $\frac{22}{15}$  1.2598 (Perkin, C. J. 45, 457). S.V. 110-39. M.M. 8.003 at 16° (P.). From the alcohol and HI or P and I (Pierre a. Pechot, *J. Ph.* [4] 13, 9; Wurtz, A. 93, 114; Chapman a. Smith, C. J. 22, 153). At 220° it partially changes to tertiary butyl bromide (Eltetoff, B. 8, 1241).

**Tertiary butyl bromide**  $CMe_3I$ . (72°). S.G.  $\frac{20}{15}$  1.215;  $\frac{22}{15}$  1.2020;  $\frac{25}{15}$  1.1892. V.D. 4.7 (obs.). M.M. 8.238 at 18°. From isobutylene and  $HI$ Br (Rozeboom, B. 14, 2396). From tri-methyl carbinol and  $PBr_3$  (Reboul, C. R. 93, 69).

**Reactions.**—1. Readily decomposes into  $HI$ Br and isobutylene. This occurs when it is treated with  $Ag_2O$ , with  $KIO$ , with  $NEt_3$ , or with  $Zn$  and water (Butlerow, Z. 1867, 362).—2. With  $ZnO$  it forms tri-isobutylene,  $C_6H_{12}$ .—3. With water, even in the cold, it forms tertiary butyl alcohol.

**BUTYL BUTYRATE** *n*. BUTYRIC ACID.

**ISO-BUTYL CARBAMINE**  $C_4H_9NC$ . (c. 116°). S.G.  $\frac{15}{15}$  .787. Preparation and properties like those of ethyl carbamine. Less readily attacked by  $HCl$  than ethyl carbamine (Gautier, A. 152, 221; *Bl.* [2] 11, 241; Z. [2] 5, 445).

**n-BUTYL CARBOXYLATE**  $(Pr.C_4H_9)_2CO_2$ . (207° cor.). at 740 mm. S.G.  $\frac{20}{15}$  .941 (Lieben a. Rossi, A. 165, 112).

**Isobutyl carbonate**  $(Pr.C_4H_9)_2CO_2$ . (190° cor.). S.G.  $\frac{15}{15}$  .919. From isobutyl iodide and  $Ag_2CO_3$  (De Clermont, A. Ch. [3] 44, 336). From isobutyl alcohol and  $CyCl$  (Humann, A. Ch. [3] 44, 340). From sodium isobutylate and chloropierin (Röse, A. 205, 253; cf. Wurtz, A. 93, 119).

**Isobutyl-orthocarbonate**  $(Pr.C_4H_9)_3C$ . (245° cor.). S.G.  $\frac{20}{15}$  .900. The chief product of the action of chloropierin on sodium isobutylate (Röse, A. 205, 253).

**BUTYL-CHLORAL** *v.* TRI-CHLORO-BUTYRIC ALDEHYDE.

**n-BUTYL CHLORIDE**  $C_4H_9Cl$  *i.e.*  $CH_3CH_2CH_2CH_2Cl$ . Mol. w. 92.5. (78° cor.). S.G.  $\frac{20}{15}$  .907;  $\frac{14}{15}$  .897 (Linnemann, A. 161, 197). S.V. 114.3 (Ramsay). From *n*-butyl alcohol and  $HI$ Cl (L.; cf. Lieben a. Rossi, A. 158, 161). From *n*-butane and chlorine (Schöyen, A. 138, 235).

**Isobutyl chloride**  $(CH_3)_2CH.C_4H_9Cl$ . (69°). S.G.  $\frac{15}{15}$  .880 (Linnemann);  $\frac{15}{15}$  .8836;  $\frac{25}{15}$  .8739 (Perkin, C. J. 45, 455). M.M. 6.144 at 21°. H.F. p. 45,370. H.F. v. 43,050 (*Th.*). S.V. 114.26 (R. Schiff, B. 19, 562). From isobutyl alcohol and  $HCl$  or  $PCl_5$  (Wurtz, A. 93, 113; Pierre a. Puchot, C. R. 72, 832).

**Tertiary butyl chloride**  $(CH_3)_3C.Cl$ . (51°). S.G.  $\frac{15}{15}$  .8471;  $\frac{15}{15}$  .8368. M.M. 6.257 at 15°.

**Formation.**—1. By action of chlorine on  $(CH_3)_3CH$  (Butlerow, J. 1864, 497).—2. By heating isobutylene,  $(CH_3)_2C:CH_2$ , with conc.  $HCl$  at 100° (Salesky, A. 165, 92; B. 5, 480; Le Bel, *Bl.* [2] 28, 462; Puchot, A. Ch. [5] 28, 549).—3. From tri-methyl-carbinol and  $AcCl$  or  $PCl_5$ .—4. From isobutyl iodide and  $ICl$  (Linnemann, A. 162, 18).

**Properties.**—With water (5 vols.) at 100° it is readily converted into tertiary butyl alcohol (Butlerow, A. 144, 33). It partakes, therefore, somewhat of the character of an acid chloride.

**BUTYL-CHLORO-** *v.* **CHLORO-BUTYL-**

**BUTYL-CINCHONIC ACID** *v.* **BUTYL-QUINOLINE-CARBOXYLIC ACID.**

**BUTYL-CRESOL** *v.* **METHYL-BUTYL-PHENOL.**

**ISO-BUTYL CYANATE**  $Pr.C_4H_9.N.CO$ . (110°). From isobutyl iodide and silver cyanate (Brauner, B. 12, 1877).

**Tertiary butyl cyanate**  $(CH_3)_3C.N.CO$ . (86° cor.). S.G.  $\frac{20}{15}$  .8676. The chief product of the action of isobutyl iodide on silver cyanate (B.)

**BUTYL CYANIDE** *v.* **VALERONITRILE.**

**n-BUTYLENE**  $C_4H_8$  *i.e.*  $CH_3CH_2CH_2CH_2$ . Vinyl-ethane. Ethyl-ethylene. Mol. w. 56. (c. -4°). Occurs in the oils deposited from compressed coal-gas (Colson, *Bl.* [2] 48, 52; C. R. 104, 1286).

**Formation.**—1. By boiling *n*-butyl iodide with alcoholic  $KOH$  (Grabowsky a. Saytzeff, A. 179, 325; Lieben a. Rossi, A. 158, 164).—2. From bromo-ethylene and  $ZnEt_2$  (Chapman, C. J. 20, 28; Wurtz, Z. [2] 5, 407).—3. Together with secondary butyl alcohol by the action of  $HNO_2$  on *n*-butyl-amine (Meyer, B. 10, 136).

**Properties.**—Gas. Forms with Br a dibromide (167°).  $HI$  forms  $CH_3CH_2CH_2CH_2I$ .

$\psi$ -Butylene  $CH_3CH:CH.C_4H_9$ . ( $\beta$ )-Butylene. *s*-Di-methyl-ethylene. (1°).

**Occurrence.**—In the oils from compressed coal-gas (Colson, C. R. 104, 1286).

**Formation.**—1. From secondary butyl iodide and alcoholic  $KOH$ ,  $Ag_2O$  and water, or  $AgOAc$  (De Luynes, A. 129, 200; 132, 275; Lieben, A. 150, 108; 151, 121).—2. Together with isobutylene by distilling *n*- or *iso*-butyl alcohol with  $ZnCl_2$  (Nevolt, *Bl.* 24, 122; Le Bel a. Greene, *Am.* 2, 23; *Bl.* [2] 20, 306).—3. By heating secondary butyl alcohol.—4. From  $MeI$ , allyl iodide, and Na, small quantities of the two other butylenes being also formed (Wurtz, *Bl.* [2] 8, 265; Grosheintz, *Bl.* [2] 29, 201).—5.  $ILSO$ , acting on isobutyl alcohol forms (1 vol. of)  $CH_3CH:CH.C_4H_9$ , and (2 vols. of)  $(CH_3)_2C:CH_2$  (Kononoff, *Bl.* [2] 34, 333; cf. Puchot, A. Ch. [5] 28, 508).—6. By boiling isobutyl iodide with  $NaO$  (Eltetoff, *Bl.* [2] 34, 347).

**Properties.**—Gas. Br gives  $C_4H_8Br_2$  (156°-159°).  $HI$  gives  $C_4H_9Cl$ ,  $C_4H_9Br$ ,  $C_4H_9I$ .

**Isobutylene**  $(CH_3)_2C:CH_2$ . *u*-Di-methyl-ethylene. (-6°). S.G.  $\frac{15}{15}$  .637 (Puchot). H.F. p. 10,660. H.F.v. 8920 (*Th.*). V.D. 1.93 (calc. 1.94). Occurs in the oils obtained by compressing oil-gas (Faraday, T. 1825, 440) or coal-gas (Colson, *Bl.* [2] 48, 52; cf. Prunier, *Bl.* [2] 19, 109).

**Formation.**—1. By electrolysis of potassium

valerate (V. lbe, *A.* 69, 269).—2. From *sec*- or *tert*-butyl alcohol and  $\text{H}_2\text{SO}_4$  or  $\text{ZnCl}_2$  (Wurtz, *B.* 3, 107; Kononoff, *Bl.* [2] 34, 333; Lermor, *Bl.* A. 196, 117; Puchot, *A. Ch.* [5] 28, 508; *C. R.* 85, 757; Scheschukoff, *Bl.* [2] 45, 181; cf. Nevolé, *Bl.* [2] 24, 122).—3. Together with ethylene and propylene by passing fusel oil through a red-hot tube (Wurtz, *A.* 104, 249; Butlerow, *A.* 145, 277).—4. From *iso*- or *tert*-butyl iodide and alcoholic KOH (De Luynes, *C. R.* 56, 1175; *A. Ch.* [4] 2, 385; Butlerow, *A.* 144, 19; *Z.* [2] 6, 236).—5. By heating dimethyl-acrylic acid to 210°–220° during 25–30 hours (Gorhoff a. Kessler, *Bl.* [2] 41, 392).

**Preparation.**—Isobutyl iodide is run into boiling alcoholic KOH and the gas collected.

**Properties.**—(Gas, sl. sol. water, v. sol. alcohol, v. e. sol. ether and  $\text{HIOAc}$ ).

**Reactions.**—1. Conc. HCl at 100° forms *tert*-butyl chloride.—2. Conc.  $\text{HI}$  aq absorbs it, forming *tert*-butyl iodide and tri-methyl carbinol (Scheschukoff, *Bl.* [2] 46, 823).—3. Conc.  $\text{H}_2\text{SO}_4$  (3 pts.) mixed with water (1 part) absorbs it, and on diluting with water and distilling *tert*-butyl alcohol is got.  $\text{H}_2\text{SO}_4$  (5 pts.) mixed with less water (1 pt.) forms much dodecylene.—4. Br in  $\text{CS}_2$  forms  $\text{C}_4\text{H}_9\text{Br}_2$  (148°) and  $\text{C}_4\text{H}_9\text{Br}_3$  (173°–183°) at 235 mm. (Nevolé, *C. R.* 83, 65; Norton a. Williams, *Am. J.* 88).—5.  $\text{HClO}$  forms a chloro-butyl alcohol (137°) (Butlerow, *A.* 144, 1; *Z.* [2] 6, 236; Henry, *Bl.* [2] 26, 23).—6.  $\text{CrO}_3$  gives acetone, oxalic acid, acetic acid, &c. (Zeidler, *A.* 197, 251).—7. Cl forms isobutenyl chlorides  $\text{C}_4\text{H}_7\text{Cl}$  (Scheschukoff, *J. R.* 16, 488).

**Combinations.**— $(\text{C}_4\text{H}_9)_2\text{Al}_2\text{Cl}_2$  From ethylene,  $\text{AlCl}_3$  and HCl (Gustavson, *J. R.* 16, 97).— $(\text{C}_4\text{H}_9)_2\text{AlBr}_2$ : oil. S.G. 2.1. V. p. 147.

**BUTYLENE ALCOHOL** v. *Di-tert*-BUTANE.

**BUTYLENE DIAMINE**  $\text{C}_4\text{H}_{12}\text{N}_2$ .

i.e.  $\text{C}_4\text{H}_8(\text{NH}_2)_2$  (?). (above 140°). From ethylene cyanide, tin, and HCl (Fairley, *C. J.* 17, 362; could not be obtained by Ladenburg, *B.* 16, 1150, or Lellmann a. Würthner, *A.* 228, 22).— $\text{B}'_2\text{H}_2\text{PtCl}_2$ .

**BUTYLENE BROMIDE** v. *Di-bromo*-BUTANE.

**BUTYLENE TRI-CARBOXYLIC ACID**

$\text{CH}_3\text{CH}:\text{C}(\text{CO}_2\text{H})\text{CH}(\text{CO}_2\text{H})_2$ . *Ethylidene-ethenyl-tri-carboxylic acid*. [185°]. Formed by the action of  $\alpha$ -chloro-crotonic ether upon sodium malonic ether, and saponification of the product (Hjelt, *B.* 17, 2833). V. sol. water, m. sol. ether.— $\text{A}'''\text{Ag}_2$ : flocculent pp.— $\text{A}'''\text{Ca}_2$  and  $\text{A}'''\text{Ba}_2$ : easily soluble powders.

*Mono-ethyl ether*  $\text{A}'''\text{H}_2\text{Et}$  3aq: [70°]: large triclinic crystals,  $a:b:c = .9111:1: .7553$ .— $\text{A}'''\text{H}_2\text{Et}$  aq [145°].

*Tri-ethyl ether*  $\text{Et}_3\text{A}'''$ . (286°).

**BUTYLENE GLYCOL** v. *Di-oxy*-BUTANE.

**BUTYLENE CHLORHYDRIN** v. **CHLORO-BUTYL ALCOHOL**.

**BUTYLENE CYANAMINE**  $\text{C}_4\text{H}_8\text{N}_4$ . [173°]. Formed by heating guanidine isovalerate at 225°. Trimetric needles, m. sol. cold water. Converted by conc.  $\text{H}_2\text{SO}_4$  into butylene guanamide  $\text{C}_4\text{H}_{11}\text{N}_3\text{O}_2$ , whence  $\text{HNO}_3$  forms cyanuric acid (Bandrowski, *B.* 9, 240).— $\text{B}'\text{HCl}$ — $\text{B}'\text{AgNO}_3$ .— $\text{B}_2\text{H}_2\text{SO}_4$ .

**BUTYLENE HYDRATE** v. *Sec*-BUTYL ALCOHOL.

**BUTYLENE NITRITE** (?)  $\text{C}_4\text{H}_8\text{N}_2\text{O}$ . From isobutylene and conc.  $\text{HNO}_3$  (Haitinger, *M.* 2, 287).

**Butylene nitrite** (?) [96°]. Formed by boiling petroleum of Tiflis with  $\text{HNO}_3$  (Beilstein a. Kurbatoff, *B.* 14, 1621).

**IS-BUTYLENE OXIDE**  $\text{C}_4\text{H}_8\text{O}$  i.e.  $\text{O} < \text{CMe}_2 > \text{CH}_2$ .

(52°). S.G. 2.8311. From isobutylene with successive treatment with  $\text{IClO}$  and KOH (Eltékoff, *Bl.* [2] 23; *J. R.* 1, 368). Water, at ordinary temperatures, unites with it, forming di-oxybutane.

**s-Butylene oxide**  $\text{O} < \text{CHMe} > \text{CHMe}$ . (57°). S.G. 2.

8314. Formed similarly from  $\text{CH}_3\text{CH}:\text{CH}:\text{CH}_2$  (E.). Water a. 100° forms di-oxy-*tert*-butane  $\text{CH}_3\text{CH}(\text{OH})\text{CH}(\text{H})\text{CH}_3$ .

**BUTYL ENNYL KETONE**  $\text{C}_{11}\text{H}_{20}\text{O}$  (?) or  $\text{C}_6\text{H}_5\text{CO}.\text{C}_5\text{H}_{11}$  ( $\text{C}_6\text{H}_5$ ). *Amyl valerate*. (209°). S.G. 12.845. From CO on sodium amylate,  $\text{NaOC}_5\text{H}_{11}$ , at 160° (Geuther a. Fröhlich, *A.* 202, 301). Liquid, does not combine with  $\text{NaHSO}_3$ .

**BUTYL ETHER** v. BUTYL OXIDE.

**BUTYL-FORMIC ACID** v. VALERIC ACID.

**BUTYL-GLYCERIC ACID** v. *Di-oxy*-BUTYRIC ACID.

**BUTYL-GLYCIDIC ACID** v. *Di-oxy*-BUTYRIC ACID.

**BUTYL GLYCOL** v. *Di-oxy*-BUTANE.

**BUTYL-GLYOXALINE**  $\text{C}_4\text{H}_8(\text{C}_6\text{H}_5)_2\text{N}_2$ . *Gly-oxal-amyline*. [217°]. Flat needles. Sl. sol. water. Prepared by the action of valeric aldehyde-ammonia on glyoxal (Radziszewski, *B.* 16, 747; 17, 1291). Br forms  $\text{C}_{11}\text{H}_{10}\text{Br}_2\text{N}_2$  [158°] and  $\text{C}_{11}\text{H}_{10}\text{Br}_3\text{N}_2$  [217°].

Salts.— $\text{B}'\text{HCl}$  [136°].— $\text{B}'\text{HBr}$  [100°].— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$  [190°].— $\text{B}'_2\text{H}_2\text{PtCl}_2$ .

**ISO-BUTYL DIGUANIDE**  $\text{C}_4\text{H}_8\text{N}_4$  i.e.

$\text{C}_6\text{H}_5\text{N}_3(\text{C}_6\text{H}_5)$ . The sulphate of the copper derivative  $\text{Cu}(\text{C}_6\text{H}_5\text{N}_3)_2\text{H}_2\text{SO}_4$  is formed by the action of aqueous  $\text{CuSO}_4$  and isobutylamine on dicyandiamide at 100° (Smolka, *M.* 4, 815). Alkaline syrup, absorbing  $\text{CO}_2$  from the air.

Salts.— $\text{B}'_2\text{H}_2\text{SO}_4$  1.5aq. S. 26.3 at 16°. Colourless transparent leaflets.— $\text{B}'_2\text{H}_2\text{SO}_4$  1.5aq.— $\text{B}'\text{HCl}$ . [216°]. S. 40 at 16°.— $\text{B}'_2\text{HCl}$ . [191°]. Deliquescent.— $\text{B}'_2\text{H}_2\text{PtCl}_2$  aq: golden four-sided tables.— $\text{B}'_2\text{H}_2\text{CrO}_4$  aq.— $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$ .

**Metallic derivatives**  $\text{Cu}(\text{C}_4\text{H}_8\text{N}_4)_2$ : silky red needles, sl. sol. water, sol. dilute acids.— $\text{Cu}(\text{C}_4\text{H}_8\text{N}_4)_2\text{HNO}_3$ .— $\text{Cu}(\text{C}_4\text{H}_8\text{N}_4)_2\text{H}_2\text{Cl}_2$  aq.— $\text{Cu}(\text{C}_4\text{H}_8\text{N}_4)_2\text{H}_2\text{SO}_4$ : carmine-red grains. S. 26 at 18°.— $\text{Cu}(\text{C}_4\text{H}_8\text{N}_4)_2\text{H}_2\text{SO}_4$  aq: pale red grains.— $\text{Cu}(\text{C}_4\text{H}_8\text{N}_4)_2\text{H}_2\text{SO}_4$  3aq: light rose-red crystals.

**n-BUTYL HEPTYL-OXIDE**  $\text{C}_{17}\text{H}_{34}\text{O}$  i.e.  $\text{C}_7\text{H}_{15}.\text{O}.\text{C}_4\text{H}_9$ . (205.7°). S.G. 8.8023. S.V. 271.3. C.E. (0°–10°) .00097 (Dobriner, *A.* 243, 8).

**BUTYL-HYDRO-ANTHRANOL** v. BUTYL-ANTHRANOL DIHYDRAIDE.

**ISO-BUTYL HYPOPHOSPHATE**  $(\text{C}_4\text{H}_9)_2\text{P}_2\text{O}_5$ . S.G. 12.125. From isobutyl iodide and  $\text{Ag}_3\text{P}_2\text{O}_5$  at 140° (Sänger, *A.* 232, 12). Oil. Decomposed by hot water.

**iso-butyl-hypophosphate of barium**

$(\text{C}_4\text{H}_9)_2\text{BaHP}_2\text{O}_5$  5aq. Needles.

**BUTYLIDENE-ACETO-ACETIC ETHER** v. p. 24.

**ISO-BUTYLIDENE-AMIDO-BENZOIC ACID**  $\text{C}_{11}\text{H}_9\text{NO}_2$  i.e.  $\text{Pr}.\text{CH}:\text{N}.\text{C}_6\text{H}_4.\text{CO}_2\text{H}$ . [145°–150°]. From amido-benzoic acid and iso-butyric aldehyde (Schiff, *A.* 210, 114). Slender needles, decomposed by cold dilute alkalis.

**TRI-ISO-BUTYLIDENE DI-AMINE** *v. Hydrobutyramide* under **ISOBUTYRIC ALDEHYDE**.  
**ISO-BUTYLIDENE CHLORIDE** *v. Di-chloro-isobutane*.

**ISO-BUTYLIDENE-METHYLENE-ANILINE** *v. Di-phenyl-isopropyl-metaprazol-tetrahydride*.

**n-BUTYL IODIDES**  $\text{C}_4\text{H}_9\text{CH}_2\text{CH}_2\text{CH}_2\text{I}$ . Mol. w. 184. ( $131^\circ$  c.f.). S.G.  $\frac{4}{3}$  1.617 (Brühl);  $\frac{2}{3}$  1.6476. S.V. 128.2. C.F. ( $0^\circ-10^\circ$ ) 0.0098 (Dobriner, A. 243, 26).  $\mu_s$  1.510.  $R_\infty$  54.47. From *n*-butyl alcohol and HI (Linne-mann, A. 161, 196).  $\text{ICl}_3$  at  $250^\circ$  acts on it thus:  $\text{C}_4\text{H}_9\text{I} + 11\text{ICl}_3 = 2\text{C}_4\text{H}_9\text{Cl} + 9\text{HCl} + 12\text{ICl}$  (Krafft, B. 10, 805).

**Secondary n-butyl iodide**  $\text{CH}_3\text{CH}_2\text{CH}(\text{I})\text{CH}_3$ . (118°). S.G.  $\frac{4}{3}$  1.626;  $\frac{20}{4}$  1.592;  $\frac{30}{4}$  1.579 (Lieben);  $\frac{1}{4}$  1.632;  $\frac{20}{4}$  1.600 (Luynes). V.D. 6.6 at  $20^\circ$  (obs.). **Formation**.—1. By distilling erythrite with HI (De Luynes, A. 125, 252; Bl. 2, 3).—2. From ethyl-chloro-ethyl ether  $\text{CH}_3\text{CH}_2\text{Cl.CEtH.O.Et}$  and HI at  $140^\circ$  (Lieben, A. 150, 87).—3. From *n*-butylene and HI (Wurtz, A. 152, 23).

**Isobutyl iodide**  $(\text{CH}_3)_2\text{CHCH}_2\text{I}$ . (120°). S.G.  $\frac{4}{3}$  1.606 (Brühl);  $\frac{15}{4}$  1.6139;  $\frac{25}{4}$  1.6007 (Perkin, C. J. 45, 462).  $\mu_s$  1.506.  $R_\infty$  54.41. S.V. 128.28 (Schiff, B. 19, 564). C.F. ( $0^\circ-20^\circ$ ) 0.0110 (Brauner, A. 192, 69). M.M. 12.199 at  $19.4^\circ$ . From isobutyl alcohol and HI. Distils constantly with 21 pts. water at  $96^\circ$  (Pierre a. Puchot, C. R. 74, 224). Treated with  $\text{AgNCS}$  gives a product,  $(\text{CH}_3)_2\text{CHCH}_2\text{NCS}$ , which on saponification yields isobutylamine and, in greater quantity, tertiary butylamine (B.). Heated with lead oxide it yields pseudo-butylene besides iso-butylene (Elteckoff, Bl. [2] 34, 347).

**Tertiary butyl iodide**  $\text{Me}_3\text{CI}$ . (100°). S.G. 1.571. **Formation**.—From tertiary butyl alcohol and HI.

**Preparation**.—By passing isobutylene (*q. v.*) into fuming HI, cooled with ice and well shaken (Markownikoff, Z. [2] 6, 29).

**Reactions**.—1. If the iodide (20 g.) be shaken with water (30 g.) for two days it dissolves, being converted into the alcohol:  $\text{Me}_3\text{CI} + \text{H}_2\text{O} = \text{Me}_3\text{C.OH} + \text{HI}$  (Dobbin, C. J. 37, 237).—2. With dry ZnO it forms tri-isobutylene.—3. With sodium it forms isobutylene, tri-isobutylene, and hydrogen, with small quantities of a hydrocarbon not absorbable by  $\text{H}_2\text{SO}_4$  (Dobbin).—4. Moist  $\text{Ag}_2\text{O}$ , Zn and water, and  $\text{AgOAc}$ , form isobutylene (Butlerow, Z. [2] 6, 237).—5. With  $\text{MeOH}$  at  $100^\circ-110^\circ$  it gives MeI and trimethyl carbinol (Bauer, A. 220, 163).—6. With  $\text{MeOAc}$  at  $110^\circ$  it forms isobutylene, HOAc and MeI.

**DI-BUTYL-KETINE** *v. Di-methyl-di-butyl-pyrazine*.

**DI-ISOBUTYL KETONE**  $\text{C}_8\text{H}_{18}\text{O}$  *i.e.*  $\text{C}_4\text{H}_9\text{CO.C}_4\text{H}_9$ . **Valerone**. Mol. w. 142. (182°). S.G. 22 833. Formed, in small quantity, by distilling calcium valerate (6 pts.) with CaO (1 pt.) (Löwig, P. 42, 412; Ebersbach, A. 106, 268; Schmidt, B. 5, 600). Does not combine with  $\text{NaHSO}_4$ .

**DI-ISOBUTYL-KETONE-SULPHONIC ACID**  $\text{O}_2\text{H}(\text{HSO}_3)-\text{CO}-\text{C}_4\text{H}_9(\text{HSO}_3)$ . The sodium salt is formed by leaving phorone in contact with a saturated solution of  $\text{NaHSO}_4$  for 2 or 3 weeks. It forms colourless prisms (A' Na<sub>2</sub> 249); soluble in water and alcohol (Pinner, B. 15, 593).

**BUTYLACTIC ACID** *v. Oxy-butyric acid*.  
**BUTYL-LUTIDINE** *v. Di-methyl-butyl-pyridine*.

**n-BUTYL-MALONIC ACID**  $\text{C}_6\text{H}_8\text{O}_4$  *i.e.*  $\text{C}_4\text{H}_9\text{CH}(\text{CO}_2\text{H})_2$ . [101°]. Prepared by saponification of the nitrile  $\text{C}_4\text{H}_9\text{CH}(\text{CN})\text{CO}_2\text{Et}$  obtained by the action of KCN on chlorohexoic ether. Thick prismatic crystals. V. sol. water, alcohol, and ether. It gives a reddish-violet colouration on warming with  $\text{H}_2\text{SO}_4$ . At about  $150^\circ$   $\text{CO}_2$  is evolved and it is converted into caproic acid.

**Salts**.— $\frac{1}{2}$  Ba: white plates. S. 2.98 at  $24^\circ$ .—A' Pb: very sparingly soluble white glistening plates. S. 0.11 at  $20^\circ$ . A' Cuag: blue glistening plates. S. 0.86 at  $22^\circ$ .—A' Ag<sub>2</sub>: white pp. S. 1.19 at  $23^\circ$  (Hell a. Lump, B. 17, 2217).

**Isobutyl-malonic acid**  $\text{PrCH}_2\text{CH}(\text{CO}_2\text{H})_2$ . [107°]. From its ether (Hjelt, J. 1882, 875).

**Ethyl ether Et<sub>2</sub>A'**. (225°). S.G. 12.983. From sodium malonic ether and isobutyl iodide.

**n-BUTYL MERCAPTAN**  $\text{C}_4\text{H}_9\text{SH}$ . Mol. w. 90. (98°). S.G.  $\frac{4}{3}$  858;  $\frac{10}{4}$  813 (Saytzeff a. Grabowsky, A. 171, 257; 175, 351).  $\text{HNO}_3$  gives butane sulphonic acid.

**Isobutyl mercaptan** (88°). S.G. 12.848 (Humann, A. 95, 256);  $\frac{20}{4}$  8357 (Nasini, G. 13, 301). V.D. 3.10 (obs.).  $R_\infty$  27.47 (N.). Formed by distilling  $\text{K}(\text{C}_4\text{H}_9)\text{SO}_3$  with aqueous  $\text{KHS}$ .— $\text{KSC}_4\text{H}_9$ .— $\text{Hg}_2(\text{C}_4\text{H}_9\text{S})_2$ : pearly scales.— $\text{Pb}(\text{C}_4\text{H}_9\text{S})_2$ : yellow crystalline pp.

**Secondary butyl mercaptan** (85°). S.G. 11.830. From sec-butyl iodide and  $\text{KHS}$ .— $\text{C}_4\text{H}_9\text{SAg}$ .— $(\text{C}_4\text{H}_9\text{S})_2\text{Hg}$  [189°] (Reymann, B. 7, 1287).

**TETRA - ISOBUTYL - METHYLENE - DI-AMINE**  $\text{C}_{12}\text{H}_{28}\text{N}_2$  *i.e.*  $\text{N}(\text{C}_4\text{H}_9)_2\text{CH}_2\text{N}(\text{C}_4\text{H}_9)_2$ . (215°-255°).  $\frac{1}{2}$  From 'trioxymethylene' (formal paraldehyde) and di-isobutylamine (Ehrenberg, J. pr. [2] 36, 117).— $\text{B}''\text{H}_2\text{PtCl}_6$  [198°]. Forms with  $\text{CS}_2$  a compound  $\text{C}_{12}\text{H}_{28}\text{N}_2\text{CS}_2$  [54°].

**BUTYL - MUSTARD OIL** *v. Butyl thio-carbamide*.

**ISO-BUTYL-NAPHTHALENE**  $\text{C}_{14}\text{H}_{16}$  *i.e.*  $\text{C}_{10}\text{H}_7(\text{C}_4\text{H}_9)$ . (280°). Prepared together with ( $\alpha$ - $\alpha$ ) and ( $\alpha$ - $\beta$ )-dinaphthyl by heating naphthalene and isobutyl chloride in presence of aluminium chloride. Colourless oil, very slightly volatile in steam. Picric acid compound; [96°] aggregates of golden needles (Wegscheider, M. 5, 236).

**ISO-BUTYL NITRATE**  $\text{C}_4\text{H}_9\text{NO}_3$ . (123°). S.G. 2 1.038. From  $\text{AgNO}_3$ , urea, and isobutyl iodide (Wurtz, A. 93 120; Chapman a. Smith, Z. 1869, 433).

**ISO-BUTYL NITRITE**  $(\text{CH}_3)_2\text{CHCH}_2\text{O.NO}$ . (67°). S.G. 2 891. H.F. p. 47,800. H.F.v. 44,900 (Th.) (Chapman a. Smith, Z. 1869, 433; Pribram a. Handl, M. 2, 658; Bertoni a. Truffi, G. 14, 23).

**Tertiary butyl nitrite**  $(\text{CH}_3)_3\text{C.O.NO}$ . (63°) (B.); (76°-78°) (T). S.G. 2 8914 (B.). Formed together with a little of the isomeric nitrobutane ( $110^\circ-130^\circ$ ) by distilling tertiary butyl iodide with silver nitrite (Tscherniak, A. 180, 155; B. 7, 962). Prepared by distilling tertiary butyl alcohol (1 mol.) with glycyl tri-nitrite (1 mol.) (Bertoni, G. 15, 357).

**BUTYL-PSEUDO-NITROLE** *v. Nitroso-nitro-butane*.

**BUTYL-NITROLIC ACID** *v.* Nitroso-nitro-butane.

***n*-BUTYL-OCTYL-OXIDE**  $C_8H_{17}.O.C_8H_{17}$ . (225-7°). S.G.  $\frac{2}{3}$  8069. S.V. 295-7. C.E. (0°-10°) 00037 (Dobrinier, A. 243, 9).

**ISO-BUTYL OXALATE** *v.* Oxalic acid.**ISO-BUTYL-OXAMIC ACID**

$PrCH_2.NH.CO.CO_2H$ . From oxalic ether (1 mol.) and dry isobutylamine (1 mol.) at 160° (Malbot, C. R. 104, 229). —  $CaA_2$ .

**Di-isobutyl-oxamic acid**

$(PrCH_2)_2N.CO.CO_2H$ . Similarly prepared from di-isobutylamine (M.).

**DI-ISO-BUTYL-OXAMIDE**  $(PrCH_2.NH)_2C_2O_2$ .

[167°]. From oxalic ether (1 mol.) and isobutylamine (2 mols.). Acute plates, insol. boiling water; may be sublimed (Malbot, C. R. 104, 228).

**DI-BUTYL OXIDE**  $(C_4H_9)_2O$ . Mol. w. 130.

(141°). S.G.  $\frac{2}{3}$  784 (Lieben & Rossi, A. 165, 110);  $\frac{2}{3}$  7865. S.V. 197-3. C.E. (0°-10°) 00109 (Dobrinier, A. 243, 8).

**Di-isobutyl oxide** (100°-104°). From isobutyl iodide and  $KO_2H_3$ , or  $Ag_2O$  (Wurtz, A. 93, 117).

**Di-*sec*-butyl oxide** (121°). S.G.  $\frac{21}{3}$  756. From aldehyde hydrochloride and  $ZnEt_2$  (Kessel, A. 175, 56; B. 7, 291).

***p*-ISO-BUTYL-PHENOL**  $C_9H_9.C_6H_5.OH$ .

[99°]. (231°) (S.); (237°) (L.). 1. From amido-isobutyl-benzene by the diazo-reaction (Studer, A. 211, 242; B. 14, 1474, 2187).—2. From phenol (100 g.), isobutyl alcohol (80 g.) and  $ZnCl_2$  (240 g.) (Liebmann, B. 14, 1842; 15, 150, 1991; Dobrzycki, J. pr. [2] 36, 330). Needles (from alcohol). Volatile with steam. V. sol. alkalis. Gives a pp. with bromine-water, but no colour with  $FeCl_3$ . Is antiseptic.  $PCl_5$  gives chloro-iso-butyl-benzene, which on oxidation gives *p*-chloro-benzoic acid. Gives a di-nitro-derivative [93°]. Fused with  $P_2O_5$  it gives phenol and isobutylene. Ammonia and  $ZnCl_2$  give  $C_9H_9.C_6H_5.NH_2$  (Lloyd, B. 20, 1254).

**Methyl ether**  $C_9H_9.C_6H_5.OMe$ . (215-5°).

S.G.  $\frac{22}{3}$  937.

**Ethyl ether**  $C_9H_9.C_6H_5.OEt$ . (235°) (S.);

(242°) (L.).

**Benzoyl derivative**  $C_9H_9.C_6H_5.OBz$ .

[83°] (S.); [80°] (Kreysler, B. 18, 1717; [335°]; [344°] (K.). White plates (from alcohol).

**Acetyl derivative**  $C_9H_9.C_6H_5.OAc$ . (245°).

S.G.  $\frac{24}{3}$  999.

**ISO-BUTYL-PHENOL SULPHONIC ACID**

$C_9H_9.C_6H_5(OH).SO_3H$ . From isobutyl phenol and  $H_2SO_4$  (Liebmann, B. 15, 1990). —  $BaA_2$  2uq.

**ISO-BUTYL-PHENYL-AMINE** *v.* AMIDO-PHENYL-BUTANE.**Di-isobutyl-di-phenyl-amine**

$(C_9H_9.C_6H_5)_2NH$ . (290°-315°). Thick oil. Formed together with  $C_9H_9.(C_6H_5)_2NH$  by heating oxy-phenyl-isobutane  $C_9H_9.(C_6H_5)_2OH$  [1:1] with ammoniacal zinc (or  $ZnCl_2$  and  $NH_4Br$  (or  $NH_4Cl$ ) at 320°-330°; the yield is 20-25 p.c. —  $B_2H_3.Cl_2.PtCl_4$ : yellow needles.

**Acetyl derivative**  $(C_9H_9.C_6H_5)_2NAc$ : [75°]; glistening white plates; sl. sol. water, v. sol. alcohol and benzene (Lloyd, B. 20, 1255).

**DI-ISO-BUTYL-DI-PHENYL CYANAMIDE**

$C_{21}H_{25}N_3$ , i.e.  $C(NC_9H_9.CH_2.Pr)_2$ . **Carbo-di-phenisobutyl-imide**. [189°]. Formed by boiling a solution of di-isobutyl-di-phenyl-thio-urea in benzene with  $PbO$  (Pahl, B. 17, 1242). Colour-

less crystals. Sol. hot benzene, sl. sol. ether. By warm dilute alcohol it is converted into di-isobutyl-di-phenyl-urea. With amines it combines to form guanidines. Heated with  $CS_2$  at 170° it yields isobutyl-phenyl-thio-carbimide.

**ISO-BUTYL-PHENYLENE-DIAMINE**

$C_9H_9.(NH_2)(NH_2.C_6H_5)$ . [39°]. Formed by the reduction of *p*-nitroso-iso-butylaniline (Wacker, A. 243, 239). Plates (from ether); can be distilled. Its chloride forms white plates; v. sol. water, sl. sol. alcohol, insol. ether.

**DI-*p*-ISO-BUTYL-DI-PHENYL-GUANIDINE**

$HN.C(NH.C_9H_9.C_6H_5)_2$ . **Di-phenisobutyl-guanidine**. [173°]. Formed by heating an alcoholic solution of di-*p*-isobutyl-di-phenyl-thiourea with  $NH_3$  and lead oxide (Pahl, B. 17, 1240). Colourless plates. V. sol. alcohol and benzene. —  $B_2H_3.Cl_2.PtCl_4$ : yellow crystalline pp.

**Tri-*p*-iso-butyl-tri-phenyl-guanidine**

$C_9H_9.C_6H_5.N.C(NH.C_9H_9.C_6H_5)_3$ . **Tri-phenisobutyl-guanidine**. [164°]. Obtained by digesting an alcoholic solution of di-*p*-isobutyl-di-phenyl-thiourea with *p*-isobutylphenyl-amine and lead oxide (P.). Small white needles. V. sol. benzene and hot alcohol. —  $B_2H_3.Cl_2.PtCl_4$ : yellow needles.

**ISO-BUTYL-PHENYL-( $\beta$ )-NAPHTHYL-THIOUREA**  $C_9H_9.NH.CS.NH.C_6H_4.C_6H_5$ . **Phenisobutyl-( $\beta$ )-naphthyl-thiourea**. [152°]. Prepared by warming an alcoholic solution of ( $\beta$ )-naphthyl-thio-carbimide and isobutylphenyl-amine (Mainzer, B. 16, 2026). White plates. Sol. boiling alcohol. By phosphoric acid it is split up into isobutylphenyl-thio-carbimide, ( $\beta$ )-naphthyl-thio-carbimide, isobutylphenyl-amine, and ( $\beta$ )-naphthylamine.

**ISO-BUTYLPHENYL-PHENYL-THIOUREA** *v.* PHENYL-ISOBUTYLPHENYL-THIOUREA.**TRI-ISO-BUTYLPHENYL-PHOSPHATE**

$PO(OC_9H_9.C_6H_5)_3$ . (above 400°). Obtained by heating isobutyl-phenol with  $POCl_3$ ; the yield is 90 p.c. of the theoretical (Kreysler, B. 18, 1700). Thick liquid. V. sl. ether, benzene, and warm alcohol; sl. sol. petroleum-ether.

**TE. RA-ISO-BUTYLPHENYL SILICATE**

$Si(OC_9H_9.C_6H_5)_4$ . (c. 380°). Obtained by heating isobutyl-phenol with  $SiCl_4$ ; the yield is 70 p.c. of the theoretical (Hertkorn, B. 18, 1692). Thick colourless oil. V. sol. benzene, chloroform,  $CS_2$ , etc.

***p*-ISO-BUTYL-PHENYL-THIOCARBIMIDE**

$SC.NC_9H_9.(C_6H_5)$ . **Phenisobutyl-mustard-oil**. [42°]. [277°]. Formed by heating di-*p*-isobutyl-di-phenyl-thiourea with phosphoric acid (Pahl, B. 17, 1235). Long white needles. V. sol. alcohol and ether.

**DI-*p*-ISO-BUTYL-DI-PHENYL-THIOUREA**

$SC(NH.C_9H_9.C_6H_5)_2$ . **Di-phenisobutyl-thiourea**. [193°]. Formed by cobating an alcoholic solution of *p*-isobutylphenyl-amine with  $CS_2$  (Pahl, B. 17, 1235). Fine white needles. Sol. ether and benzene, sl. sol. alcohol, insol. water.

**DI-*p*-ISO-BUTYL-DI-PHENYL-UREA**

$OC(NH.C_9H_9.C_6H_5)_2$ . **Di-phenisobutyl-urea**. [284°].

**Formation**.—1. By the action of carbonyl chloride on *p*-isobutylphenyl-amine dissolved in benzene.—2. By cobating an alcoholic solution of the thiourea with mercuric oxide (Pahl, B. 17, 1240). Colourless needles. Sol. hot alcohol, insol. water.

**ISO-BUTYL-PHOSPHINE**  $C_4H_9PH_3$ . (62°). Prepared, together with the following, from isobutyl iodide, ZnO, and  $PH_3I$  at 100° (Hofmann, B. 6, 296). Resembles ethyl-phosphine in preparation and properties.

Di-isobutyl phosphine  $(C_4H_9)_2PH_2$ . (113°).

Tri-isobutyl phosphine  $(C_4H_9)_3P$ . (215°). From the preceding and isobutyl iodide.

Tetra-isobutyl-phosphonium iodide  $(C_4H_9)_4PI$ . Crystalline.

**ISO-BUTYL-PHOSPHINIC ACID**  $C_4H_9PO_3H_2$ . [100°]. Paraffin-like solid (Hofmann, B. 6, 304).

—A'Ag. Amorphous pp.

Di-isobutyl-phosphinic acid  $(C_4H_9)_2PO_3H$ . Oil. —A'Ag. Amorphous.

**ISOBUTYL PHOSPHITE**. *Dichloride*.  $C_4H_9O.PCl_2$ . (155°). S.G.  $\rho$  1.191. A by-product in the conversion of isobutyl alcohol into isobutyl chloride by  $PCl_3$  (Menschutkin, A. 139, 347).

**DI-ISO-BUTYL-PINACONE**  $C_{11}H_{20}O_2$  i.e.  $Pr.CH_2.CH_2.CMe(OH).CMe(OH).CH_2.CH_2.Pr$ . *Di-oxy-tetra-decane*. *Tetra-decylene glycol*. [30°]. (268°). A product of the action of Na upon methyl iso-amyl ketone (Rohn, A. 190, 305; Purdie, C. J. 39, 468). Needles, insol. water.

**BUTYL-METAPYRAZOLONE** v. Di-oxy-BUTYL-METAPYRAZOL.

(Py. 3)-**ISO-BUTYL-QUINOLINE**  $C_{13}H_{11}N$

i.e.  $C_6H_5 \begin{matrix} \diagup \\ \text{CH:CH} \\ \diagdown \end{matrix} \begin{matrix} \diagup \\ N=C(C_4H_9) \\ \diagdown \end{matrix}$  (271°). Colourless oily

liquid. Formed by distilling its (Py. 1)-carboxylic acid with lime (Doebner, B. 20, 280; A. 242, 282).

**Picric acid compound**  $B'C_6H_3N_3O_6$ . [161°]. Lemon-yellow plates (from alcohol). — $(B'HCl)_2PtCl_6$ . Orange-red needles (from water).

(Py. 3)-**ISO-BUTYL-QUINOLINE** — (Py. 1) — **CARBOXYLIC ACID**

$C_{11}H_{11}NO_2$  i.e.  $C_6H_5 \begin{matrix} \diagup \\ C(CO_2H):CH \\ \diagdown \end{matrix} \begin{matrix} \diagup \\ N=C(C_4H_9) \\ \diagdown \end{matrix}$ . *Isobutyl-*

*cinchonic acid*. [186°]. Formed by the action of isovaleric aldehyde upon pyruvic acid and aniline. White satiny plates (containing  $1\frac{1}{2}$  aq) (Doebner, B. 20, 279; A. 242, 280). — $B'HCl_3$  aq: plates. — $B'_2H_2PtCl_6$ . —A'Ag.

**ISO-BUTYL SILICATE**  $(PrCH_2)_2SiO_4$ . (c. 258°). S.G.  $\rho$  1.953. From  $SiCl_4$  and isobutyl alcohol (Cahours, C. R. 77, 1408). Slowly decomposed by water.

**BUTYL SULPHATES**

*n*-Butyl-sulphuric acid  $Pr.CH_2.SO_3H$ .

Salt. — $BaA'$  aq: crystalline plates. S.G.  $\rho$  1.778 (Lieben a. Rossi, A. 165, 116; Clarke, B. 11, 1506).

**Isobutyl sulphuric acid**  $Pr.CH_2.SO_3H$ . From the alcohol and  $H_2SO_4$  (Wurtz, C. R. 35, 310). — $KA'$ : laminae (from alcohol).

**Chloride**  $C_4H_9O.SO_2Cl$ . From isobutyl alcohol and  $SO_2Cl_2$  (Beckmann, J. pr. [2] 15, 34). Liquid.

***n*-BUTYL SULPHIDE**  $(C_4H_9)_2S$ . Mol. w. 146. (182°). S.G.  $\rho$  0.852;  $\rho$  0.839 (Saytzeff, A. 171, 253). From butyl iodide and  $K_2S$ .

**Isobutyl sulphide**  $(Pr.CH_2)_2S$ . (171° i. V.). S.G.  $\rho$  0.836. Formed by distilling isobutyl sulphate with conc. aqueous KHS (Beckmann, J. pr. [2] 17, 445).

**Secondary butyl sulphide**  $(OMeEtH)_2S$  (165°). S.G.  $\rho$  0.832. Combines with MeI (Reymann, B. 7, 1288).

**Isobutyl disulphide**  $(CH_3Pr)_2S_2$ . (220°) (Spring a. Legros, B. 15, 1938).

**ISO-BUTYL SULPHOCYANIDE**  $CH_2Pr.S.CN$ . (175°) (Reimer, B. 3, 757).

***n*-BUTYL SULPHONE**  $(C_4H_9)_2SO_2$ . [44°]. From fuming  $HNO_3$  and  $(C_4H_9)_2S$  (Grabowsky, A. 175, 348).

Di-isobutyl sulphone  $(C_4H_9)_2SO_2$ . [17°]. (265° i. V.). S.G.  $\rho$  1.006. Di-isobutyl sulphoxide (100 pts.) is dissolved in water (1000 pts.) and oxidised by  $KMnO_4$  (63 pts.) dissolved in water (1900 pts.). Excess of permanganate destroyed by sodic formate and the sulphone extracted by ether. The yield is quantitative (Beckmann, J. pr. [2] 17, 448).

**Properties**. —White plates. Not affected by reducing agents

***n*-BUTYL SULFOXIDE**  $(C_4H_9)_2SO$ . [32°]. From  $HNO_3$  (S.G. 1.3) and  $(C_4H_9)_2S$  (Grabowsky, A. 175, 348).

Di-isobutyl sulphoxide  $(C_4H_9)_2SO$ . [69°]. From di-isobutyl sulphide (1 pt. and (2 pts. of  $HNO_3$  (S.G. 1.4) in the cold. Extracted with ether after neutralisation. The yield is quantitative (Beckmann, J. pr. [2] 17, 446).

**Properties**. —Yellow needles. Soluble in 2 parts of cold water, but separates as an oil on warming. Readily reduced to di-iso-butyl sulphide.

**BUTYL SULPHURIC ACID** v. BUTYL SULPHATE.

**DI-ISO-BUTYL-THETINE**

$CO_2H.CH_2.S(C_4H_9)_2(OH)$ . The hydrobromide is a syrup formed by the action of isobutyl sulphide on bromo-acetic acid at 100°. Lead converts it into crystalline  $C_{10}H_{20}SO_5PbBr_2$  and  $C_{10}H_{20}SO_5PbBr_2$  (Letts, Pr. E. 28, 588).

***n*-BUTYL THIO-CARBIMIDE**  $CH_2Pr.NCS$ . Mol. w. 115. (167°). Formed by boiling *n*-butylamine with  $CS_2$  and alcohol. Evaporating the alcohol and heating the residue with aqueous  $HgCl_2$  (Hofmann, B. 7, 508).  $NH_3$  gives butyl-thio-urea [79°].

**Isobutyl thio-carbimide**  $CH_2Pr.NCS$ . (162°). S.G.  $\rho$  0.937. Similarly prepared. (II).  $NH_3$  gives isobutyl-thio-urea [94°].

**Secondary isobutyl thio-carbimide**

$CHMeEt.NCS$ . (160°). S.G.  $\rho$  0.944. Similarly prepared. It is the essential constituent of the oil of scurvy-grass or spoon-wort (from *Cochlearia officinalis*) (Hofmann, Z. [2] 5, 400; B. 2, 102).  $NH_3$  gives butyl-thio-urea [135°].

**Tertiary butyl thio-carbimide**  $CMe_2Pr.NCS$ . [11°]. (140°). S.G.  $\rho$  0.900 (Budneff, J. R. 11, 179; B. 12, 1023).

**BUTYL THIO-CARBONIC ACID** v. THIO-CARBONIC ACID.

***n*-BUTYL-THIOPHENE**  $C_8H_7$   $(C_4H_9)$  (181°). S.G.  $\rho$  0.957. Colourless oil. Formed by the action of sodium on a mixture of iodothiophene and butyl bromide (Meyer a. Kreis, B. 17, 1561).

**BUTYL-THIO-UREAS**. The preparation and properties of these bodies are analogous to those of the corresponding ethyl thio-ureas (q. v.).

***n*-Butyl thio-urea**  $CH_2Pr.NH.CS.NH_2$ . [79°]. From butyl thio-carbimide and  $NH_3$  (Hofmann, B. 7, 512).

**Isobutyl thio-urea** [94°] (H.).

**Sec-butyl thio-urea** [138°] (H.).

**Tert-butyl thio-urea**  $\text{CMe}_3\text{NH.CS.NH}_2$ . [165°] (Rudneff, *Bl.* [2] 33, 300). Prisms, sol. alcohol.

**Di-tert-butyl thio-urea**  $\text{SC(NHOMe)}_2$ . [162°]. From tert-butyl-amine,  $\text{CS}_2$ , and alcohol. Formed also by the action of tert-butyl thiocarbimide on tert-butyl-amine (Rudneff, *Bl.* [2] 33, 300).

**m-ISO-BUTYL-TOLUENE**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)$ . [1.3]. (187°) (K. a. B.); (194°) (R.); (185°) (E.). **Methyl-isobutyl-benzene**. Colourless liquid. Occurs in oil of resin (Kelbe a. Baur, *B.* 16, 619, 2559; Renard, *A. Ch.* [6] 1, 250). Prepared by the action of isobutyl bromide on toluene in presence of  $\text{AlBr}_3$  (K. a. B.). Formed by diazotising methyl-isobutyl-phenyl-amine and treating the diazo-salt with an excess of  $\text{SnCl}_4$  (Effront, *B.* 17, 2329). On oxidation with  $\text{HNO}_3$  it first gives m-iso-butyl-benzoic acid and finally isophthalic acid (Kelbe a. Pfeiffer, *B.* 19, 1723).

**p-(Iso?)-Butyl-toluene**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)$ . [1.4]. (178°). Occurs in oil of resin.  $\text{HNO}_3$  oxidises it to p-toluic acid (Kelbe a. Baur, *B.* 16, 2562).

**p-Isobutyl-toluene** (c. 195°)? Formed by heating toluene with isobutyl alcohol and  $\text{ZnCl}_2$  (Goldschmidt, *B.* 15, 1067). Formed, together with the m-isomeride, by the action of isobutyl bromide on toluene in presence of  $\text{AlBr}_3$  (Kelbe a. Pfeiffer, *B.* 19, 1725).  $\text{HNO}_3$  oxidises it to p-isobutyl-benzoic acid.

**m-ISO-BUTYL-TOLUENE-SULPHONIC ACID**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)(\text{SO}_3\text{H})$  [1.3:2]. [76°]. Small hygroscopic plates. Formed by sulphonation of m-iso-butyl-toluene.

**Salts**.— $\text{KA}'_2$ : large soluble pearly plates. — $\text{NaA}'$ : needles. — $\text{CuA}'_2$ : large blue soluble plates. — $\text{BaA}'_2$ : small plates, sl. sol. cold water and alcohol. — $\text{PbA}'_2$ : pearly plates.

**Amide**: [5°], small plates, soluble in water (Kelbe a. Baur, *B.* 16, 2560).

**p-(Iso?)-Butyl-toluene-sulphonic acid**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)(\text{SO}_3\text{H})$  [1.4:2]. Obtained by sulphonation of p-isobutyl-toluene.

**Salts**.— $\text{KA}'_2$ : small easily soluble plates. — $\text{NaA}'_2$ : small sparingly soluble plates. — $\text{CuA}'_2$ : easily soluble blue crystals. — $\text{PbA}'_2$ : small plates, sol. hot water.

**Amide**: [113°], large pearly plates, sl. sol. hot water (Kelbe a. Baur, *B.* 16, 2563).

#### ISO-BUTYL-o-TOLUIC ACID

$\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)\text{CO}_2\text{H}$  [1.3:6]. [140°]. Formed by saponification of its nitrile (Effront, *B.* 17, 2334). White needles. V. sol. alcohol and ether, sl. sol. hot water, insol. cold water. — $\text{A}'\text{Ag}$ : colourless plates, v. sol. hot water.

**Nitrile**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)\text{CN}$  [1.3:6]. [60°]. (248°). **Formation**.—1. By distilling the formyl derivative of methyl-isobutyl-phenyl-amine with zinc-dust. —2. By heating isobutyl-tolyl-thiocarbimide with copper powder (E.). Long white needles. V. sol. alcohol and ether, sl. sol. hot petroleum-ether, insol. water.

**Isobutyltoluic acid**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)\text{CO}_2\text{H}$  [1.5:6]. [132°]. Formed by saponification of its nitrile (Effront, *B.* 17, 2343). White silvery plates. V. sol. alcohol and ether, sl. sol. hot water. — $\text{A}'\text{Ag}$ : colourless plates, sol. hot water.

**Nitrile**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)\text{CN}$  [1.5:6]. (248°).

**Formation**.—1. By distilling the formyl derivative of methyl-isobutyl-phenyl-amine with zinc-dust. —2. By heating isobutyl-tolyl-thiocarbimide with copper-powder (Effront, *B.* 17, 2343). Colourless oil, solidifies on freezing to a white crystalline mass. V. sol. alcohol and ether.

**ISOBUTYL-TOLUIDINE** v. METHYL-ISOBUTYL-PHENYL-AMINE.

**BUTYL-TOLYL-AMINE** v. METHYL-BUTYL-PHENYL-AMINE.

#### ISO-BUTYL-TOLYL-THIOCARBIMIDE

$\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)\text{NCS}$  [1.3:6]. [16°]. (275°) (20°). Formed by the action of phosphoric acid on di-isobutyl-di-tolyl-thiourea (Effront, *B.* 17, 2336). Long white needles. V. sol. alcohol and ether.

**Isobutyl-tolyl-thiocarbimide**  $\text{C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5)\text{NCS}$  [1.5:6]. [41°]. (267°). Formed by heating di-isobutyl-di-tolyl-thiourea with phosphoric acid (Effront, *B.* 17, 2345). White crystalline solid. V. sol. alcohol and ether.

#### DI-ISOBUTYL-DI-TOLYL-THIOUREA

$\text{SC(NH.C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5))_2$ . [184°]. Formed by digesting methyl-isobutyl-phenyl-amine with  $\text{CS}_2$  in alcoholic solution (Effront, *B.* 17, 2335). Long thin silky needles. V. sol. ether, sl. sol. alcohol.

#### Di-isobutyl-di-tolyl-thiourea

$\text{SC(NH.C}_6\text{H}_4(\text{CH}_3)(\text{C}_2\text{H}_5))_2$ . [175°]. White needles. Sol. hot alcohol. Formed by digesting methyl-isobutyl-phenyl-amine with an alcoholic solution of  $\text{CS}_2$  (Effront, *B.* 17, 2344).

**ISO-BUTYL-UREA**. *Valeryl derivative*  $\text{NH}(\text{C}_2\text{N}_3)\text{CO.NH}(\text{C}_6\text{C}_2\text{H}_5)$ . [102°]. Flat needles. Sol. alcohol and ether, sl. sol. water. Formed by the action of KOH on a mixture of (2 mols. of) valeramide (isopropyl-acetamide) and (1 mol. of) bromine (Hofmann, *B.* 15, 758).

#### Isobutyl-di-butyl-urea

$\text{CMe}_3\text{NH.CO.NH.C}_2\text{H}_5\text{Pr}$ . [163°]. From tert-butyl cyanate and isobutylamine (Brauner, *B.* 12, 18, 5).

**Di-tert-butyl-urea**  $(\text{CMe}_3\text{NH})_2\text{CO}$ . [242°]. From tert-butyl cyanate and tert-butylamine (B.).

**ISO-BUTYL-XANTHAMIDE** v. THIO-CARBONIC ETHERS.

#### BUTYRAL v. BUTYRIC ALDEHYDE.

#### BUTYRAMIDE v. Amide of BUTYRIC ACID.

**Di-isobutyramide**  $(\text{C}_2\text{H}_5\text{CO})_2\text{NH}$ . [174°].

Formed by the action of ammonia on isobutyryl chloride (Hofmann, *B.* 15, 981). Long needles. Sublimable. Sol. alcohol. On distillation it splits up into isobutyric acid and isobutyronitrile.

#### n-BUTYRIC ACID $\text{C}_4\text{H}_8\text{O}_2$ i.e.

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ . Mol. w. 88. [c. -3°]. (162° cor.). S.G.  $\frac{40}{4}$ : 9594 (Brühl);  $\frac{5}{4}$ : 976 (Zander);  $\frac{15}{16}$ : 9670;  $\frac{35}{16}$ : 9588 (Perkin, *C. J.* 45). C.E. (0°-10°) 00104 (Z.). M.L. 4.472 at 18.8° (P.).  $\mu_p$  1.4025.  $R_\infty$  35.50. S.V. 107.85 (R. Schiff, *A.* 220, 105); 108.3 (Z.). S.H. 140.46 0° (Schiff, *A.* 234, 300).

**Occurrence**.—1. Butter contains 2 p.c. of glyceryl butyrate (Chevreul, *A. Ch.* [2] 23, 23). Rancid butter contains free n-butyric acid (Grünzweig, *A.* 162, 193). —2. In crude wood vinegar. —3. In perspiration (Schotten, *J.* 1852, 701). —4. In muscular juice (Scherer, *A.* 69, 196). —5. In the contents of the large intestine. —6. As hexyl butyrate in oil got from fruit of *Heracleum*

*giganteum*.—7. The fruit of *Pastinaca sativa* contains octyl butyrate.—8. In cheese (e.g. of Limburg) (Iljenko, A. 63, 268).

A great many vegetable and animal juices and oils contain butyric acid, but in most cases it has not been determined whether the acid is *n*- or *iso*-butyric acid (Gorup-Besance, A. 69, 369; Klinger, A. 106, 18; Krämer, *Ar. Ph.* [2] 54, 9; Wagner, *J. pr.* 46, 155; Scherer, A. 69, 196; Rebling, *Ar. Ph.* [2] 92, 83; 93, 300).

**Formation**.—1. A product of the fermentation of sugar, starch, milk, fibrin, and most kinds of vegetable and animal matter (Pelouze & Gélis, *A. Ch.* [3] 10, 436; Lerch, A. 49, 215; Bonaparte, *C. R.* 21, 1070; Erdmann & Marchand, *J. pr.* 29, 468; Wurtz, A. 52, 291; Scharling, A. 49, 313; Schubert, *J. pr.* 33, 256; Sullivan, *J.* 1858, 280; Rithausen, *Z.* [2] 4, 314).—2. By fermentation of calcium lactate:  $2C_2H_5O_2 = C_2H_5O_2 + 2CO_2 + 2H_2$ .

3. Along with *n*-butyl alcohol by the fermentation of glycerin through a Schizomycetes in presence of  $CaCO_3$  (Fitz, B. 9, 1348).—4. By the action of  $CrO_3$  on albuminoids (Guckelberger, A. 64, 68).—5. By the action of  $HNO_3$  on fats (Redtenbacher, A. 59, 49) and on Chinese wax (Buckton, *C. J.* 10, 166).—6. By oxidation of conine (Blyth, A. 70, 89).—7. By the aceto-acetic ether synthesis (Frankland & Duppa, A. 138, 218) v. ACETO-ACETIC ETHER.—8. By passing CO over a mixture of  $NaOEt$  and  $NaOAc$  at  $200^\circ$ :  $C_2H_5NaO + C_2H_5NaO_2 + CO = CH_3NaO_2 + C_2H_5NaO_2$  (Fröhlich, A. 202, 306).

**Preparation**.—Sugar (6 kilos.), water (26 litres), and tartaric acid (30 g.) are left for some days, after which there is added putrid cheese (250 g.), sour skimmed milk (8 kilos.), and chalk (3 kilos.). The mixture is kept at  $30^\circ$  to  $35^\circ$  with occasional stirring. Calcium lactate is first formed, and this is afterwards decomposed with evolution of hydrogen (v. **Formation** 2); at the end of six weeks the evolution of gas ceases and the whole is now converted into calcic butyrate (Bensch, A. 61, 177, cf. Grillon, A. 165, 127; Lieben & Rossi, A. 153, 146; and Fitz, B. 11, 52). Crude butyric acid may be purified by etherification, followed by saponification of the butyric ether ( $121^\circ$ ) (Dannoff, B. 19, 2552).

**Properties**.—Liquid, miscible with water, of powerful unpleasant smell. Separated from aqueous solution by  $CaCl_2$ . Its barium salt is more soluble in alcohol than those of formic, acetic, or propionic acids. Its calcium salt is *ppd.* by boiling a solution saturated in the cold.

**Reactions**.—1. Boiled with  $HNO_3$ , it gives succinic acid (Dessaignes; Erlenmeyer, A. 180, 207).—2. With  $CrO_3$  it gives  $CO_2$  and acetic acid (Grünzweig & Hecht, B. 11, 1053).—3. With  $MnO_2$  and dilute  $H_2SO_4$  it gives propyl butyrate (Veiel, A. 148, 164).—4. The silver salt decomposes on dry distillation according to the equation:  $4C_2H_5CO_2Ag = 3C_2H_5CO_2H + CO_2 + C + 4Ag$  (Iwig & Hecht, B. 19, 240).—5. Distillation over zinc-dust at  $350^\circ$  gives di-propyl ketone, propylene, CO, H, and other products (Jahn, B. 13, 2115).

**Salts**.— $NaA'$ .— $KA'$ . S.  $125^\circ$  at  $15^\circ$ . Very deliquescent.— $MgA'$ . Very soluble plates.— $CaA'$ . S.  $20^\circ$  at  $0^\circ$ ;  $18^\circ$  at  $22^\circ$ ;  $15^\circ$  at  $60^\circ$ ;  $16^\circ$  at  $100^\circ$  (Chancel & Parmentier, *C. R.* 104, 474; Hecht, A. 213, 69). Trimetric needles.— $CaA'_2$ . aq. S.  $19^\circ$  at  $22^\circ$ .— $(CaA'_2)_2(C_2H_5O_2)$  5aq.  $CaA'_2 \cdot CaCl_2(C_2H_5O_2)_4$ .— $CaCl_2(C_2H_5O_2)_2$  2aq (Lie-

ben, M. 1, 926).— $SrA'$ . S.  $40^\circ$  at  $22^\circ$ .— $BaA'_2$  4aq. S.  $40^\circ$  at  $14^\circ$ . S. (alcohol)  $11^\circ$ . Trimetric.— $BaA'_2$  2aq.— $BaA'_2O_2H_2O_2$  (Mixer, *Am.* 8, 343).— $BaA'_2CaA'_2$ . Regular octahedra (Fitz, B. 13, 1314).  $ZnA'_2$  2aq. S.  $11^\circ$  at  $16^\circ$ . Monoclinic prisms. Gives *pp.* of basic salt on boiling.— $PbA'_2$ . oil.— $PbA'_2 \cdot 2PbO$ .— $PbA'_2 \cdot 2CaA'_2$ . cubes.— $CuA'_2$  2aq. Monoclinic.— $CuA'_2$  aq. Triclinic (Alth, A. 91, 176).— $CuA'_2 \cdot 2Cu(AsO_3)_2$  (Wöhler, A. 94, 44).— $AgA'$ . S.  $343^\circ$  at  $4^\circ$ . Needles or monoclinic prisms.

**Methyl ether** ( $102^\circ$ ). S.G.  $\frac{9}{10}$  9194 (Gartenmeister, A. 233, 249);  $\frac{9}{10}$  9194 (Elsässer, A. 218, 314);  $\frac{1}{10}$  948 (Kahlbaum, B. 12, 344);  $\frac{20}{10}$  8962 (Brühl);  $\frac{15}{10}$  9037;  $\frac{25}{10}$  8945 (Perkin, C. J. 45, 483). M.M.  $5^\circ$  387 at  $16^\circ$  (W.). S.V.  $120^\circ$  35 (R. Schiff, A. 220, 332).  $\mu_D$  1.3936 (Brühl).  $R_\infty$  43.11 (B.). C.E. ( $0^\circ$ – $10^\circ$ ) 001156 (E.).

**Ethyl ether**.—Mol. w. 116. ( $121^\circ$  cor.). V.D. 3.99 (for 4.00) (S.). S.G.  $\frac{9}{10}$  9004 (Gartenmeister);  $\frac{9}{10}$  8996 (E.);  $\frac{15}{10}$  898 (Linnemann & Zotta, A. 161, 178);  $\frac{20}{10}$  8892 (B.);  $\frac{15}{10}$  8849;  $\frac{25}{10}$  8762 (P.). M.M.  $6^\circ$  477 at  $16^\circ$  (P.). S.V.  $150^\circ$  23 (S.).  $\mu_D$  1.4007.  $R_\infty$  50.33 (B.). C.E. ( $0^\circ$ – $10^\circ$ ) 001162 (E.). Smells like pine-apples, in which it occurs as well as in other fruits.

**Allyl ether** ( $140^\circ$ ) (Chalours & Hofmann, *Tr.* 1857, 555; A. 102, 296); ( $145^\circ$ ) (Berthelot & De Luca, A. 100, 360).

**Propyl ether** ( $143^\circ$  cor.). S.G.  $\frac{9}{10}$  8930 (E.);  $\frac{15}{10}$  1.879 (Linnemann, A. 161, 53). S.V.  $173^\circ$  85 (S.). C.E. ( $0^\circ$ – $10^\circ$ ) 001077 (E.).

**Iso-propyl ether**. ( $128^\circ$ ). S.G.  $\frac{9}{10}$  879;  $\frac{15}{10}$  865 (Silva, A. 153, 135).

**n-Butyl ether** ( $165^\circ$  cor.). S.G.  $\frac{9}{10}$  8878 (G.);  $\frac{15}{10}$  876 (Linnemann, A. 161, 195);  $\frac{20}{10}$  889;  $\frac{25}{10}$  872 (Lieben & Rossi, A. 158, 170). S.V.  $197^\circ$  8 (G.). C.E. ( $0^\circ$ – $10^\circ$ ) 00105 (G.).

**Iso-butyl ether** ( $156^\circ$ ) (S.);  $157^\circ$  (E.). S.G.  $\frac{9}{10}$  8818 (E.);  $\frac{20}{10}$  880;  $\frac{15}{10}$  866 (Grünzweig, A. 162, 207). S.V.  $197^\circ$  66 (S.);  $200^\circ$  53 (E.). C.E. ( $0^\circ$ – $10^\circ$ ) 001093 (E.). **Velocity of bromination**: Ureel, B. 13, 1693.

**n-Amyl ether** ( $184^\circ$ ). S.G.  $\frac{9}{10}$  8832. C.E. ( $0^\circ$ – $10^\circ$ ) 00099. S.V.  $222^\circ$  3 (Ga.).

**Iso-amyl ether**. ( $176^\circ$ ) (Delffs, A. 92, 278); ( $178^\circ$ ) (E.). S.G.  $\frac{9}{10}$  8823 (E.). S.V.  $221^\circ$  52 (E.). C.E. ( $0^\circ$ – $10^\circ$ ) 001014 (E.).

**Hexyl ether**. ( $205^\circ$ ). S.G.  $\frac{9}{10}$  8825. C.E. ( $0^\circ$ – $10^\circ$ ) 00096. S.V.  $246^\circ$  4 (Ga.). From *Heraclium* (Franchimont & Zincke, A. 163, 198).

**Heptyl ether** ( $225^\circ$ ). S.G.  $\frac{9}{10}$  8827. C.E. ( $0^\circ$ – $10^\circ$ ) 00093. S.V.  $270^\circ$  2 (Gartenmeister).

**Octyl ether**. ( $245^\circ$ ) (R.); ( $242^\circ$ ) (G.). S.G.  $\frac{9}{10}$  8794. C.E. ( $0^\circ$ – $10^\circ$ ) 00091. S.V.  $295^\circ$  6 (G.). From *Pastinaca sativa* (Renesse, A. 166, 80).

**Cetyl ether**. [ $20^\circ$ ]. (c.  $265^\circ$ ) at 200 m.m. S.G.  $\frac{20}{10}$  856 (Dollfus, A. 131, 285).

**Ethylene ether** v. GLYCOL.

**Ethylidene ether** v. *Di-butyl ortho-ALDEHYDE* p. 106.

**Glyceryl ether** v. GLYCERIN.

**Amide**  $C_2H_5CONH_2$ . [ $115^\circ$ ]. ( $216^\circ$ ). Prepared by heating ammonium butyrate under pressure at  $230^\circ$ ; the yield is 75 p.c. (Chancel, A. 52, 294; Buckton & Hofmann, *C. J.* 9, 241; B. 15, 982).— $Hg(C_2H_5NO)$ .

**Anilide**  $C_2H_5CO.NH(C_6H_5)$ . [ $92^\circ$ ]. Pearly plates (from dilute alcohol). Sol. ether. Formed by heating butyramide, butyric anhydride, or

chloride with aniline (Gerhardt, *A. Ch.* [3] 37, 829; Kelbe, *B.* 16, 1200).

**Chloride**  $C_4H_7COCl$ . Mol. w. 106.5. (101°). S.G.  $\frac{2}{3}$  1.0277.  $\mu_D^{20}$  1.4178.  $R_D^{20}$  41.43 (Brühl, *A.* 203, 19). From butyric acid (96 pts.) and  $PCl_5$  (100 pts.) (Burreker, *A. Ch.* [5] 26, 468; Linnemann, *A.* 161, 179). Converted by sodium-amalgam into dibutylryl ( $C_4H_9O_2$ ).  $AlCl_3$  forms crystalline  $C_4H_7O_2$  [107°] 'butyryl-butyl-butyl-butyl anhydride.'  $NaOH$  forms  $C_{12}H_{19}NaO_4$  (Combes, *C. R.* 104, 853).

**Bromide**  $C_4H_7OBr$ . (128°) (Berthelot, *J.* 1857, 344).

**Iodide**  $C_4H_7OI$  (147°) (Cahours, *A.* 101, 111).

**Anhydride**  $(C_4H_7O)_2O$ . (192°). S.G. 1.3-978. V.D. 5.88 (obs.). From sodium butyrate (4 pts.) and  $POCl_3$  (2 pts.) or  $BzCl$  (2 pts.) (Gerhardt, *A.* 87, 155). Also from butyryl chloride and butyric acid (Linnemann, *A.* 161, 179). Heated with sodium butyrate at 180° it forms di-propylketone (Perkin, *C. J.* 49, 325).

**Peroxide**  $(C_4H_7O)_2O_2$ . From butyric anhydride and  $Bz_2O_2$ . Oil (Bredie, *Pr.* 12, 655).

**Nitrile**  $C_4H_7CN$ . **Propyl cyanide**. Mol. w. 69. (119°). S.G. 1.3-795. Formed by distilling the amide or ammonium butyrate with  $P_2O_5$  (Dumas, *A.* 64, 334; Henke, *A.* 106, 272).

**Isobutyric acid**  $(CH_3)_2CHCO_2H$ . Mol. w. 88. (153° cor.). S.G.  $\frac{1}{4}$  0.9539;  $\frac{2}{3}$  0.9157 (Perkin, *C. J.* 45, 487);  $\frac{20}{100}$  0.9190 (Brühl);  $\frac{2}{3}$  0.9651 (Zander). C.E. (0°-10°) 0.0110 (Z.). S. 20 at 20°. M.M. 4.479 at 17.8° (P.). S.V. 108.57 (R. Schiff, *A.* 220, 105).  $\mu_D^{20}$  1.3979.  $R_D^{20}$  35.48 (R.). S.H. 435 at 0° (Schiff, *A.* 234, 300). *Heat of solution* 973. *Heat of neutralisation in dilute solution* 13989 (Gal. a. Werner, *Bl.* [2] 46, 801). *Vapour-pressure*: Richardson (*C. J.* 49, 173).

**Occurrence**.—1. In St. John's bread, the fruit of *Cerastoma siliqua* (Grünzweig, *A.* 158, 117; 162, 193).—2. In the root of *Arnica montana* (Sigel, *A.* 170, 345).—3. As an ether (isobutylic?) in Roman oil of chamomile (Kopp, *A.* 197, 85; Köbig, *A.* 195, 96).—4. In human excrement (Brieger, *B.* 10, 1029).

**Formation**.—1. From iso-propyl cyanide and potash (Markownikoff, *A.* 138, 361).—2. By saponifying di-methyl-aceto-acetic ether (Frankland & Duppa, *A.* 138, 337).—3. Aqueous calcium butyrate which had been heated and cooled in a sealed tube 30 or 40 times in 10 years was found to have changed to the extent of 10 p.c. into calcium isobutyrate (Erlenmeyer, *A.* 181, 126).—4. By the oxidation of pyrotaric acid (Williams, *B.* 6, 1094).

**Preparation**.—By adding  $K_2Cr_2O_7$  (4 pts.) to a cold mixture of isobutyl alcohol (3 pts.),  $H_2SO_4$  (5½ pts.) and water (15 pts.). Isobutyl isobutyrate separates. It is distilled with moist potash, and the potassium salt is distilled with strong  $H_2SO_4$  (Pierre & Puchot, *A. Ch.* [4] 23, 366).

**Properties**.—Unpleasant smelling liquid.

**Reactions**.—1. *Oxidised* by  $CrO_3$  mixture at 140° to  $CO_2$ , acetone (Popoff, *Z.* 1871, 4) and acetic acid (Erlenmeyer, *Z.* [2] 7, 57).—2. *Oxidised* by  $KMnO_4$  in alkaline solution, to  $\beta$ -oxyisobutyric acid,  $(CH_3)_2C(OH)CO_2H$ , according to Richard Meyer's rule that when the group  $CH$  is united to three carbon atoms it may be oxidised to  $CO_2H$ .—3. Calcic isobutyrate on *distillation* gives di-isopropyl-ketone, with smaller

quantities of methyl *tert*-butyl ketone, isobutyric aldehyde, and isobutyric acid (Barbaglia & Gucci, *G.* 11, 84).

**Salts**.—More soluble than those of *n*-butyric acid.— $CaA_2$  aq.: small plates. S. (of  $CaA_2$ ) 20 at 0°; 8 at 80°; 25 at 100°.— $CaA_2$  5 aq.: long monoclinic prisms (Chancel & Parmentier, *C. R.* 104, 477).— $SrA_2$  5 aq.: S. 44 at 17° (hydrated) (Grünzweig).— $BaA_2$  1 aq.: Monoclinic.— $BaA_2 \cdot HA$  [74°] (Mixer, *Am.* 8, 346).— $BaA_2 \cdot Ba(C_4H_7O)_2$  aq.:— $ZnA_2$  aq.: S. (hydrated). 17 at 20°.— $PbA_2$  S. 9 at 16°. Trimetric plates. Melts under hot water.— $AgA$  S. 93 at 16°. Plates.

**Methyl ester**. (92°). S.G.  $\frac{1}{4}$  0.9112 (Elsässer, *A.* 218, 335). C.E. (0°-10°) 0.01223 (E.). S.V. 126.5. H.F. p. 109,660. H.F. v. 116,760 (*Th.*).

**Ethyl ether**. (110°). S.G.  $\frac{1}{4}$  0.8904 (E.);  $\frac{1}{2}$  0.8758;  $\frac{2}{3}$  0.8670 (Perkin, *C. J.* 45, 487). M.M. 6.479 at 21.8° (P.). C.E. (0°-10°) 0.01156 (E.). S.V. 148.86 (E.); 150.68 (Schiff, *A.* 220, 333).

**Propyl ether**. (135°). S.G.  $\frac{1}{4}$  0.8813 (E.). C.E. (0°-10°) 0.01039 (E.). S.V. 173.7 (E.); 174.2 (S.).

**Iso-propyl ether** (120°). S.G.  $\frac{1}{4}$  0.879 (Pribram & Handl, *M.* 2, 691).

**Iso-butyl ether**. (116.6°) (E.); (149°) (S.). S.G.  $\frac{1}{4}$  0.8750 (E.). C.E. (0°-10°) 0.00994 (E.). S.V. 198.2 (S.); 196.0 (E.).

**Iso-amyl ether**. (169°) (E.). S.G.  $\frac{1}{4}$  0.8760. C.E. (0°-10°) 0.01031. S.V. 223.04.

**Benzyl ether v. p.** 493.

**Amide** [129°]. (c. 218°). Prepared by heating ammonium isobutyrate at 230° under pressure; the yield is 90 p.c. (Hofmann, *B.* 16, 982; cf. Letts, *B.* 5, 672; Münch, *A.* 180, 340; and Di-iso-butyramide).

**Bromo-amide**  $C_4H_7CO.NHBr$ . [92°]. Prepared by the action of bromine and KOH on isobutyramide (Hofmann, *B.* 15, 755). Large colourless needles, sol. ether, sl. sol. water. Decomposed by caustic alkalis into propylamine, HBr, and  $CO_2$ , but by carbonated alkalis the reaction stops half way with production of propyl cyanate.

**Iso-propyl-amide**  $PrCO.NHPr$ . [102°]. (210°). Formed by the action of acetyl chloride on di-isopropyl acetoxyim (Meyer & Warrington, *C. J.* 51, 685). Also by the action of isobutyl chloride on isopropylamine. Colourless transparent needles v. sol. alcohol and ether, n. sol. water. Sublimes at ordinary temperatures and distills without decomposition. Is decomposed by prolonged boiling with alcoholic potash into isobutyric acid and isopropylamine.

**Anilide**  $C_4H_7CO.NH(C_6H_5)$ . [103°]. From isobutyric acid and aniline (Norton, *Am.* 7, 116). Prisms.

**p-Bromo-anilide**  $C_4H_7CO.NH(C_6H_4Br)$  [144]. [128°]. From the preceding and Br (*N.*).

**Chloride**  $C_4H_7COCl$ . (92°) (Markownikoff, *Z.* 1866, 501). S.G.  $\frac{2}{3}$  1.0174 (Brühl, *A.* 203, 20).  $\mu_D^{20}$  1.4135.  $R_D^{20}$  41.41 (B.).  $ZnMe_2$  (1 mol.) followed by water converts isobutyryl chloride into a ketone  $C_{10}H_{18}O$  (190°). S.G.  $\frac{2}{3}$  0.870 (Pawlow, *A.* 189, 139).  $ZnMe_2$  (2 mols.) followed by water forms tertiary butyl alcohol and sometimes a ketone  $C_{12}H_{22}O$  (218°). S.G.  $\frac{2}{3}$  0.864.

**Bromide (117°).**

**Anhydride** ( $C_4H_6O_2$ ). (182°). S.G. 1.13  
9574 (Markownikoff, Z. 1866, 501; Tönnies a.  
Staub, B. 17, 860).

**Nitrile** ( $CH_3$ ).CH.CN. (108°). From iso-  
propyl iodide, KCN, and alcohol (Markownikoff,  
Bl. 1866, 53). From isobutyraldehyde and potas-  
sium sulphocyanide (Letts, J. 5, 669).

**BUTYRIC ALDEHYDE**  $C_4H_8O$  i.e.  
 $CH_3$ .CH<sub>2</sub>.CH<sub>2</sub>.CHO. (74°). Mol. w. 72. S.G.  
0.8170 (Brühl).  $\mu_d$  1.3893.  $n_D^{20}$  32.93. S. 37.  
Got by distilling calcium butyrate with calcium  
formate (Linnemann, A. 161, 186; Lipp, A.  
211, 355). From casein by oxidation with  $H_2SO_4$   
and  $MnO_2$  (Guckelberger, A. 63, 39).

**Reaction.**—Aqueous  $NaOH$  and  $NaOAc$   
form oily  $C_4H_7O$  (173°). It is probably  
 $Pr.CH_2.CHLi.CEt.CHO$  as it reacts with phenyl-  
hydrazine and combines with bromine (Raupen-  
strauch, M. 8, 108).

**Ammonia compound**  
( $CH_3$ ).CH.CH(OH)(NH<sub>2</sub>)<sub>3</sub>.aq. [31°]. Trimetric  
pyramids. V. sl. sol. water, v. sol. alcohol, no  
sol. ether. Deliquesce above 4°, giving off water.

**Bisulphite compound**  $C_4H_7ONaHSO_3$   
(Juslin, B. 17, 2505; Kahn, B. 18, 3364).

**Butyraldines.** Dibutyraldine  $C_8H_{16}NO$  and  
tetra-butyraldine  $C_{16}H_{32}NO_2$  are formed by the  
protracted action of alcoholic ammonia on  
butyric aldehyde (Schiff, A. 157, 352). Butyral-  
dine, on distillation, gives para-coniine  $C_8H_{13}N$ .

**Butyral**  $C_4H_6O$  (?) (95°). S.G. 22.821. A  
product of distillation of calcic butyrate (Chancel,  
A. Ch. [3] 12, 146; Limpriecht, A. 90, 111;  
93, 241). Reduces  $Ag_2O$ . Does not combine  
with  $NH_3$ . Combines with  $NaHSO_3$ .

**Reactions.**—1. Air or  $Ag_2O$  forms butyric  
acid.—2. Chlorine forms  $C_4H_7ClO$  (141°) and  
 $C_4H_7Cl_2O$  (200°).—3.  $PCl_5$  forms  $C_4H_7Cl$  (c. 100°).

**Isobutyric aldehyde** ( $CH_3$ ).CH.CHO. (64°).  
S.G. 1.15.7972;  $\mu_d$  1.3789 (Perkin, C. J. 45, 476);  
 $\mu_d$  1.3738 (Brühl, A. 203, 18). S. 11 at 20°.  
 $\mu_d$  1.3777.  $n_D^{20}$  32.89. H.F.p. 61.340. H.F.v.  
59.310. M.M. 4.321 at 19.3°.

**Formation.**—1. From isobutyl alcohol by  
chromic mixture (Pfeiffer, B. 5, 699; Michael-  
son, A. 133, 182; Pierre a. Puchot, C. R.  
70, 434).—2. By heating iso-butylene bromide,  
( $CH_3$ ).CHBr.CHBr, with water (20 vols.) at 160°  
(Linnemann a. Zotta, A. 162, 36).—3. By dis-  
tilling calcium isobutyrate (Popoff, B. 6, 1255;  
Barbaglia a. Gucci, B. 13, 1572).—4. By dis-  
tilling calcium isobutyrate with calcium formate  
(Linnemann a. Zotta, A. 162, 7).—5. By dis-  
tilling copolyphony (Tilden, B. 13, 1604).

**Preparation.**—A mixture of conc. aqueous  
 $K_2Cr_2O_7$  with an equal volume of  $H_2SO_4$  is  
slowly run into a flask containing iso-butyl  
alcohol (100 g.) and water (200 g.) until the  
layer of alcohol has disappeared. The product  
is distilled. The yield is 55 p.c. of the theo-  
retical (W. H. Perkin, jun., C. J. 43, 91; cf.  
Fossek, M. 4, 660).

**Properties.**—Pungent liquid. Forms a com-  
pound with  $NaHSO_3$  from which it is separated  
by potash without change.

**Reactions.**—1. By the action of potash (4 g.)  
in alcohol (140 g.) upon the aldehyde (50 g.) the  
following bodies may be obtained: isobutyric  
acid, an acid  $C_{12}H_{22}O_2$  (245°–255°) and an alde-  
hyde  $C_{12}H_{22}O$ .—2. If more potash (8 g.) and a

higher temperature be used, the neutral products  
are:  $C_8H_{16}O_2$ ,  $C_8H_{16}O_3$ ,  $C_{12}H_{22}O_2$ ,  $C_8H_{16}O_4$ , and  
 $C_{12}H_{22}O_3$  (W. H. Perkin, jun., C. J. 43, 101).—3.  
Aqueous potash forms an acid  $C_4H_7O_2$  (75°–80°),  
a crystalline body  $C_4H_7O_2$  [90°], and di-oxo-  
octane (Fossek, M. 3, 622).—4.  $PCl_5$  gives chloro-  
isobutylene  $Me.C.CHCl$  (68°) and di-chloro-iso-  
butane (104°)  $Me.CH.CHCl_2$  (Oeconomidis, C. R.  
92, 884).—5.  $H_2S$  and aqueous ammonia form  
isobutyraldine  $C_4H_7NS_2$  (Pfeiffer, B. 5, 700).  
6.  $CS_2$  and conc.  $NH_4Aq$  give  $NH_4.CS.SN(C_4H_7)_2$   
[91°]. Prisms, insol. water, v. sol. alcohol.—  
7. Alcohol and  $HCl$  followed by  $NaOEt$  form  
di-ethyl-ortho-isobutyric aldehyde  
 $CMc.CH.CH(OEt)_2$  (135°). S.G. 1.2.996. V.D.  
143.5, and, when some water is also present, a  
compound  $C_{12}H_{22}O$  (223°) (Oeconomidis, Bl. [2]  
36, 210; C. H. 92, 886).—8. Gives with ammonia  
a crystalline compound  $(C_4H_7)_3N_2H_2O$  (Lipp, A.  
205, 1; 211, 344; B. 13, 906; 14, 1746).  
 $7C_4H_7CHO + 6NH_3 = 6H_2O + (C_4H_7)_3N_2H_2O$ .  
When the product, 'oxy-hepta-iso-butyridene-  
amine' [32°], is heated, it first splits up into  
 $2NH_3$ ,  $C_4H_7O$  and  $2(C_4H_7)_3N_2$ . The latter is  
hydro-butyramide, an oil, nearly insoluble in  
water, v. sol. alcohol or ether. If quickly heated  
it distils at 154°, but if heated slowly it splits  
up into  $NH_3$  and  $C_4H_7N$ . Hydro-butyramide  
or tri-isobutyridene-diamine is not affected by  
boiling  $KOH$ , but dilute  $HCl$  splits it up into  
butyric aldehyde and  $NH_3$ . It is, therefore,  
 $C_4H_7:N.C_4H_7:N.C_4H_7$ . Dry  $HClN$  added to its  
etheral solution forms the dihydrochloride of  
( $Cy.C_4H_7.NH$ )<sub>2</sub> $C_4H_7$ , a body that is decomposed  
by water into isobutyric aldehyde and amido-  
valero-nitrile. When hydro-butyramide is slowly  
heated it does not, like hydro-benzamide, change  
into an isomeric, but splits up, giving  $C_4H_7N$ .  
This compound, 'iso-butenyl-butyridene-amine',  
is a liquid (145°–147°) at 715 mm., nearly  
insoluble in water, miscible with alcohol or  
ether. It is not affected by aqueous  $KOH$ ,  
but acids split it up into isobutyric aldehyde  
and  $NH_3$ . It would thus appear to be  
( $CH_3$ ).CH.CH:N.CH(C<sub>4</sub>H<sub>7</sub>)<sub>2</sub>. It combines with  
Br, forming  $C_4H_7NBr_2$ , a body that, when kept  
for a long time, and then treated with water,  
gives  $NH_4Br$ , isobutyric aldehyde and bromo-iso-  
butyric aldehyde, or rather a polymeride of the  
latter [129°]. If  $C_4H_7NBr_2$  be at once treated  
with water, the unstable liquid bromo-butyric  
aldehyde is probably formed (Lipp).

**Oxim**  $C_4H_7.CH:N(OH)$ . [139°]. Colourless  
liquid. Sol. water. Formed by the action of an  
aqueous solution of hydroxylamine on isobutyric  
aldehyde (Petracsek, B. 15, 2784).

**Description of condensation products**, ob-  
tained as above (W. H. Perkin, jun., C. J. 43, 90).  
Acid  $C_{12}H_{22}O_2$  (245°–255°). Brownish oil.  
Reduces ammoniacal  $Ag_2O$ .

Compound  $C_{12}H_{22}O_2$  (154°–157°). Oil.  
Etheral odour. Reduces ammoniacal  $Ag_2O$ .  
Combines slowly with  $NaHSO_3$ . Decomposes on  
prolonged heating. Is probably Urech's  $C_8H_{14}O$   
(B. 12, 191). With Na and wet ether, it is re-  
duced to  $C_{12}H_{22}O$  (170°–175°), an alcohol (?)  
which does not combine with  $NaHSO_3$ .

Compound  $C_{20}H_{38}O$  (223°–225°). Oil.  
Smells of camphor. Very slowly combines with  
 $NaHSO_3$ , forming needles. Reduces ammoniacal  
 $Ag_2O$ . V.D. 167 (Theory 842). With  $Ag_2O$  it

forms  $C_{22}H_{34}O_4$  (240°-242°). Oil, which with  $Ac_2O$  at 200° gives  $C_{22}H_{34}O_4$  (248°-252°). When saponified by  $KOH$ , a body  $C_{22}H_{34}O_4$  (c. 220°) is formed.

Compound  $C_{22}H_{34}O_4$  (250°-253°). Oil. V.D. (air = 1) 12.9 (Theory 13.7).

Compound  $C_{22}H_{34}O_4$  (227°-229°) at 100 mm. Thick oil. Decomposed when heated under atmospheric pressure.

Di-isobutyric di-aldehyde  $C_8H_{14}O_2$  (138°) at 18 mm. V.D. 5.2 (calc. 5.0). This polymeride of isobutyric aldehyde is obtained, together with octenoic aldehyde (?)  $C_8H_{14}O$  (150°) by heating isobutyric aldehyde with conc. aqueous  $NaOAc$  at 150° (Fossek, *M.* 2, 622). It is an oil, sol. alcohol and ether, forming a crystalline compound with  $NaHSO_3$ .

Iso-butyric paraldehyde  $(C_4H_8O)_3$  [60°] (195°). V.D. (H=1) 104.8. From iso-butyraldehyde by  $H_2SO_4$ ,  $HCl$ ,  $PCL_3$ ,  $Cl$ ,  $Br$ , or  $I$  (Barbaglia, *B.* 5, 1052; 6, 1064; *G.* 16, 430; Demtschenko, *B.* 6, 1176). Needles (from water or by sublimation). Difficultly attacked by oxidising agents (Urech, *B.* 12, 1749). Does not combine with  $NaHSO_3$  or react with  $NH_3$ . At 150° it partially changes to ordinary isobutyric aldehyde.

Iso-butyric poly-aldehyde  $(C_4H_8O)_n$ . S.G. 24.969. Prepared by leaving isobutyric aldehyde in contact with dry  $Na_2CO_3$ . Thick liquid. Sl. sol. water. Decomposed on distillation, with separation of water and formation of isobutyric aldehyde and condensation products (Urech, *B.* 12, 191, 1744; 13, 483, 590).

BUTYRIN *v.* GLYCERIN.

BUTYRO-CHLORAL *v.* TRI-CHLORO-BUTYRIC ALDEHYDE.

BUTYRO-COUMARIC ACID *v.* OXY-PHENYL-PENTENOIC ACID.

BUTYRO-CREATININE *v.* METHYL-AMIDO-BUTYRIC ACID.

BUTYRO-FURONIC ACID  $C_8H_{12}O_5$  *i.e.*  $CO_2H.CH:CH.CO.CH_2.CH_2.CH_2.CO_2H$  (?). [142°]. Prepared by treating furfural with acid with bromine-water and subsequent action of silver oxide. White crystals. Sol. water and alcohol, sl. sol. ether. By  $HI$  and  $P$  it is reduced to azelaic acid (Tocnnies, *B.* 12, 1200).

BUTYRO-LACTONE *v.*  $\gamma$ -OXY-BUTYRIC ACID.

BUTYROLIC ACID *v.* TETROLIC ACID.

BUTYRONE *v.* DI-PROPYL-KETONE.

BUTYRONITRILE *v.* Nitrile of BUTYRIC ACID.

BUTYRO-PINACONE  $C_{14}H_{26}O_2$  *i.e.*

$CPr_2(OH).CPr_2(OH)$ . Di-oxy-tetradecane. [68°]. (260°). From di-propyl-ketone, water, and  $Na$  (Kurtz, *A.* 161, 215). Crystals, smelling of camphor, sl. sol. water.

BUTYRO-THIENONE *v.* THIENYL PROPYL KETONE.

DI-BUTYRYL  $C_{22}H_{34}O_4$  *i.e.*  $Pr.CO.CO.Pr$ . Di-propyl di-ketone. (245°-260°). From butyryl chloride and sodium-amalgam or zinc (Freund, *A.* 118, 35). Yellow oil. Boiled with potash it forms butyrate of potassium and a liquid  $C_{22}H_{34}O_4$  which does not unite with  $NH_3$  or  $NaHSO_3$ .

Mono-oxim  $C_{22}H_{34}O_4.N(OH).C_2H_5$ : thick oil; can be distilled in small quantity without decomposition. A di-oxim has not been obtained (Münchmeyer, *B.* 19, 1846).

BUTYRYL-ACETOPHENONE

$C_{22}H_{34}O_4.CO.CH_2.CO.C_6H_5$ . Benzoyl-methyl-propyl-ketone. (174° at 24 mm.). S.G. 1.061 at 15°.

Colourless oil. Formed from acetophenone and butyric ether by  $EtONa$  (Beyer a. Claisen, *B.* 20, 2181).

Isobutyryl-acetophenone

$C_8H_8.CO.CH_2.CO.C_6H_5$ . Benzoyl-methyl-isopropyl-ketone. (170° at 26 mm.). Colourless liquid. Formed from acetophenone and isobutyric ether by  $EtONa$  (Beyer a. Claisen, *B.* 20, 2181).

BUTYRYL-AMIDO-BENZOIC ACID

$Pr.CO.NH.C_6H_4.CO_2H$ . [209°]. From *n*-butyric ether (20 c.c.) and *m*-amido-benzoic acid (10 g.) at 180° in sealed tubes (Pellizzari, *A.* 232, 148). Sol. water and alcohol.

BUTYRYL AMIDE *v.* BUTYRIC ACID.

BUTYRYL CHLORIDE *v.* BUTYRIC ACID.

BUTYRYL CYANAMIDE *v.* CYANAMIDE.

*n*-BUTYRYL CYANIDE  $C_4H_7NO$  *i.e.*

$Pr.CO.CN$ . [233°-137°]. From  $AgCN$  and  $PrCOCl$  (E. Moritz, *C. J.* 39, 16).

*n*-Di-butyryl di-cyanide  $(Pr.CO)_2(CN)_2$  (c. 234°). By-product in preparation of above.

Iso-butyryl cyanide  $Pr.CO.CN$ . (117°-120°). From  $PrCOCl$  (40 g.) and  $AgCN$  (50 g.). Bad yield (E. Moritz, *C. J.* 39, 13). The greater part of the product is di-iso-butyryl di-cyanide (226°-228°). S.G. .96.

BUTYRYL IODIDE *v.* BUTYRIC ACID.

BUTYRYL-MALONIC ETHER

$C_8H_8.CO.CH(CO_2Et)_2$  (247°-252°). Formed by the action of butyryl chloride upon sodio-malonic ether. By nitrous acid it is converted into isonitroso-butyryl-acetic ether (Lang, *B.* 20, 1326).

BUTYRYL PEROXIDE *v.* BUTYRIC ACID.

BUTYRYL-PROPYL-UREA *v.* Butyryl derivative of PROPYL-UREA.

BUTYRYL SULPHOCYANIDE (180°). From butyryl chloride and lead sulphocyanide. Decomposes when boiled (Miquel, *A. Ch.* [5] 11 295).

BUTYRYL-UREA *v.* UREA.

BUXEIN. An alkaloid extracted by dilute oxalic acid from the bark of the box-tree *Buxus sempervirens*. Yellowish-white crystalline substance, sol. alcohol and ether, sl. sol. water.  $HNO_3$  gives a greenish-yellow colouration turning brick-red.  $H_2SO_4$  gives a blood-red colour. Chromic acid mixture gives an orange pp. (Alessandri, *G.* 12, 96). It is perhaps identical with buxine. Barbaglia finds four alkaloids in the leaves and twigs of the box: buxine, parabuxine, buxidine, and buxinidine (*G.* 13, 249; *B.* 17, 2655).

BUXINE  $C_{22}H_{34}O_4$  (?). An alkaloid extracted by dilute oxalic acid from the leaves of the box tree. White crystalline substance, sol. alcohol and ether, sl. sol. water.  $HNO_3$  gives a purple-red colouration.  $H_2SO_4$  gives a brick-red colour. Chromic acid mixture gives a canary-yellow pp. (Alessandri, *G.* 12, 96; Barbaglia, *B.* 4, 757; Fauré, *J. Ph.* 16, 328; Courbe, *J. Ph.* 1854, 51). According to Wetz (J. 1860, 548) buxine is identical with becerine (*q. v.*).

Parabuxine  $C_{22}H_{34}O_4$  (?) An alkaloid occurring in both leaves and bark of the box tree. It is a reddish-purple amorphous resin, sol. water and alcohol, insol. ether.  $HNO_3$  gives a permanent greenish-yellow colouration.  $H_2SO_4$  gives a greenish-yellow colour becoming dark. Chromic acid mixture gives no pp.— $B''H_2SO_4$ — $B''HCl$ — $B''H_2PtCl_6$  (Pavesi a. Riondini, *G.* 4, 192; Alessandri).

C

**CACAO** *v.* **THEOBROMINE**.

**CACODYL** *v.* p. 318.

**CACOSTRYCHNINE**  $C_{21}H_{29}N_3O_6$ . A product of the action of  $HNO_3$  on strychnine (*q. v.*). Golden needles (from dilute  $HNO_3$ ) or hexagonal plates (from conc.  $HClAq$ ). Sl. sol. most menstrua, sol. alkalis, forming red solutions.— $B_2H_4.PtCl_6$  (Claus a. Glassner, *B.* 14, 773).

**CACOTHELINE**  $C_{20}H_{22}N_2O_6$ . A product of the action of  $HNO_3$  on brucine (*q. v.*). Orange laminae (containing aq). Weak base; sol. alkalis, v. sl. sol. hot water, insol. alcohol and ether.— $B_2H_4.PtCl_6$  (Strecker, *A.* 91, 76; *C. R.* 39, 52; Rosengarten, *A.* 65, 111; Claus a. Röhr, *B.* 14, 765).

**CADAVERIC ALKALOIDS** *v.* **PTOMAINES**.

**CADET'S FUMING LIQUID** *v.* p. 318.

**CADMIUM**. Cd. At. w. 111.7. Mol. w. 111.7; gaseous molecule is monatomic. [320] (Person, *A. Ch.* [3] 27, 250; Rudberg, *P.* 71, 460; v. Biensdyk, *C. N.* 20, 32). (763°–772°) (Carnelley a. Williams, *C. J.* 33, 284). S.G. (molten) 8.65, (hammered) 8.8 (Stromeyer, *S.* 22, 362; Schröder, *P.* 106, 226; 107, 113; Matthiessen, *P.* 110, 21, &c.). V.D. 55.8 (Deville a. Troost, *C. R.* 52, 920). S.H. (0° 100°) .0518 (Bunsen, *P.* 141, 1), .0567 (Regnault, *A. Ch.* [3] 26, 268). C.B. (linear, 0°–100°) .003323; (cubical for 1°) .000094 (Kopp, *A.* 81, 32; Matthiessen, *P.* 130, 50; Fizeau, *C. R.* 68, 1125). T.C. (Ag=100) 20.06 (Lorenz, *W.* 13, 422). E.C. (Hg at 0°=1) at 0°, 13.46; at 100°, 9.5 (Lorenz, *W.* 13, 422 a. 582). Heat of fusion 13,660 (Person, *P.* 76, 426). S.V.S. abt. 12.8. Emission-spectrum characterised by lines 3609.6, 3465.4, 2747.7, 2572.2, 2313.6, 2288.9 (Hartley, *T.* 1884, 63).

Cd was discovered by Stromeyer in 1817 in a specimen of zinc carbonate (*S.* 21, 297; 22, 362; *v.* also Hermann, *G. A.* 59, 95). The name *cadmium* was derived from *cadmia fossilis* by which name zinc ore was then known.

**Occurrence**.—With Zn in various native sulphides, carbonates, and silicates, especially in the Silesian zinc ores (*v.* Damour, *J. pr.* 13, 354; Stadler, *J. pr.* 91, 359; Blum, *J.* 1858, 734; Bunsen, *A.* 133, 108). CdS occurs nearly pure as *Greenockite* at Bishopston in Renfrewshire.

**Formation**.—In the distillation of crude zinc oxide with charcoal; the greater part of the Cd distils over before the Zn.

**Preparation**.— $ZnO$  containing CdO, or metallic Zn containing Cd, is dissolved in dilute  $H_2SO_4$  or  $HClAq$ ; the warm solution is saturated with  $H_2S$ ; the CdS thoroughly washed and dissolved in conc.  $HClAq$ ; most of the free HCl is removed by warming, the solution is diluted and filtered, and an excess of  $(NH_4)_2CO_3$  is added; the pp. of CdCO<sub>3</sub> is well washed, dried, and strongly heated; the CdO thus produced is mixed with  $\frac{1}{10}$  of its weight of pure powdered charcoal and heated in a retort of hard-glass or porcelain when pure Cd distils over (Stromeyer, *S.* 22, 362).

**Properties**.—White with slight blue tinge; very lustrous; soft, but harder than zinc; very

malleable, ductile, and flexible; more tenacious than tin; crystallises easily in monometric forms, chiefly the octahedron (*v.* Kümmerer, *B.* 7, 1724; also G. Rose, *P.* 85, 293). Vapour is yellow. Cd does not decompose water even at 100°; but if Cd vapour and steam are passed through a hot tube the steam is decomposed (Regnault, *A. Ch.* 62, 351). Cd oxidises slowly on the surface by exposure to air; when heated in air it burns to CdO. The atomic weight of Cd has been determined (1) by finding the V.D. of, and by analysing, CdBr<sub>2</sub> (Meyer, *B.* 12, 1292; Dumas, *A. Ch.* [3] 55, 158; Huntingt., *P. Am. A.* 17, 28); analyses of CdCO<sub>3</sub> (Lonsen, *J. pr.* 79, 281); reduction of CdSO<sub>4</sub> to CdS (*v.* Hauer, *C. C.* 1857, 897); analyses of CdO (Stromeyer, *S.* 22, 366); (2) by determining the S.H. of Cd (Bunsen, *P.* 141, 1; Regnault, *A. Ch.* [3] 26, 268); (3) by comparing, as regards crystalline form and general reactions, salts of Cd with salts of Zn, Be, Mg, and Hg. In the gaseous molecule CdBr<sub>2</sub> (this is the only compound of Cd whose V.D. has been determined) the atom of Cd is divalent. The gaseous molecule of Cd is monatomic. Cd is a distinctly metallic element; it acts on  $HClAq$ ,  $H_2SO_4$ , &c., evolving H and forming salts of the form  $CdX_2$  where  $X_2 = Cl_2, Br_2, SO_4, CO_3$ , &c.; many of these salts combine with the similar salts of the more positive metals (K, Ca, Mg, &c.) to form double salts; but few basic salts of Cd are known, the most marked are derived from such weak acids as  $H_2CrO_4$ ,  $H_2BO_3$ , &c. No compound of Cd exhibits any acidic functions.  $CdO.H_2$  acts towards acids as a salt-forming hydroxide; its heat of neutralisation by  $H_2SO_4$  is about the same as that of the corresponding hydroxide of Mn, Ni, Co, Fe, or Zn, [ $CdO.H_2Aq$ ,  $H_2SO_4Aq$ ] = 23.8° (*v. Th.* 1, 339 a. 436).  $CdO.H_2$  is dehydrated by heat; the oxide CdO is not converted to  $CdO.H_2$  by direct addition of  $H_2O$ . Cadmium is closely related to Zn, it is less positive than that metal; it is also related to Mg on one hand and to Hg on the other (*v.* **MAGNESIUM GROUP OF ELEMENTS**).

**Reactions**.—1. Heated in air, or O, CdO is produced. — 2. Heated nearly to redness in bromine, CdBr<sub>2</sub> is formed. — 3. Aqueous solutions of hydrochloric, sulphuric, or nitric, acids are decomposed by Cd with formation of chloride, sulphate or nitrate of the metal. — 4. Heated with  $SO_4Aq$  to 200° CdS is formed (Geitner, *A.* 129, 354); possibly sulphite and thiosulphate are first formed (*v.* Schweitzer, *C. N.* 23, 293; Forlos a. Gélis, *A.* 50, 260).

**Combinations**.—Most compounds of Cd are formed from the oxide or other salt. Cd combines directly with the elements O, Cl, Br, I, P, S, Se, Te, and with many metals (*v.* **CADMIUM, OXIDE** or, &c., and **CADMIUM ALLOYS** or).

**Detection and Estimation**.—Formation of the yellow sulphide, CdS, insoluble in dilute  $HClAq$  and also in solution of ammonium sulphide, characterises Cd salts. Cd is usually estimated by ppn. as CdCO<sub>3</sub> (by  $K_2CO_3Aq$ ), the pp. is strongly heated, and the CdO is weighed. Separation from other metals may be effected

by repeated pptn. by  $H_2S$ , and solution of  $CdS$  in conc.  $HClAq$ .  $Cd$  may be pptd. as oxalate; on this fact is founded a volumetric method of estimation.

**Cadmium, Alloys of.** Usually prepared by melting the metals together. Several are characterised by low melting-points. An amalgam with  $Hg$  is formed at ordinary temperatures: by dissolving  $Cd$  in warm  $Hg$ , and pressing, a crystalline amalgam, having the composition  $Hg_2Cd$ , and S.G. 12.62, is formed; by completely saturating  $Hg$  with  $Cd$ , octahedral crystals of  $Hg_2Cd$ , melting at  $77^\circ$ , are produced (Gauguin, *C. R.* 42, 430; Regnault, *C. R.* 51, 779; Crookewitt, *J. pr.* 102, 65 a. 129; Kopp, *A.* 46, 186). Easily fusible alloys with  $Bi$  agreeing in composition with the formulae  $BiCd$ ,  $Bi_2Cd$ , and  $Bi_3Cd$ , are known (Matthiessen, *P.* 110, 21). Various alloys of  $Cd$  with (1)  $Bi$  and  $Pb$ , (2)  $Bi$ ,  $Pb$  and  $Sn$ , (3)  $Bi$  and  $Sn$ , are also known ([1] Wood, *D. P. J.* 164, 108; v. Hauer, *J. pr.* 94, 436; [2] Lipowitz, *D. P. J.* 158, 376; [3] Wood, *Le.*). Alloys with  $Pb$  (Wood, *C. N.* 6, 135);  $Na$  (Sonnenschein, *J. pr.* 67, 169);  $Tl$ , and with  $Tl$  and  $Bi$  (Carstensen, *J. pr.* 102, 65 a. 129); and  $Sn$  (Rudberg, *J.* 1817, 71), have been described. An arsenide,  $AsCd$ , is said to be obtained as a faintly red-coloured alloy, S.G. 6.26, by reducing the arsenate by  $KCN$  (Descamps, *C. R.* 86, 1022 a. 1065).

**Cadmium, Arsenates of.**  $Cd_3(AsO_4)_2 \cdot 3H_2O$ , and  $Cd_2H_2(AsO_4)_3 \cdot 4H_2O$ ; v. ARSENATES, under ARSENIC, ACIDS OF.

**Cadmium, Arsenide of.**  $Cd_3As$  v. CADMIUM, ALLOYS OF.

**Cadmium, Bromide of.**  $CdBr_2$ . Mol. w. 271.2.  $[570^\circ]$  (Carnelley, *C. J.* 33, 278).  $(806^\circ-812^\circ)$  (Carnelley a. Williams, *C. J.* 34, 326). S.G.  $^{20^\circ}$  4.794 (Clarke, *Am. S.* No. 4). H.F.  $[Cd, Br^2] = 75,200$ ;  $[Cd, Br^2, Aq] = 75,610$  (Thomsen).

**Preparation.**—By heating  $Cd$  to redness in  $Br$  vapour; or by dissolving  $CdCO_3$  in  $HBrAq$  and subliming.

**Properties and Reactions.**—White, crystalline, non-hygroscopic, solid; soluble in water, ether, and alcohol; decomposed by  $HNO_3Aq$  (Bodeker a. Giesecke, *J.* 1860, 17; Croft, *P. M.* [3] 21, 355; Berthelot, *A. Ch.* 44, 387; Rammeisberg, *A.* 44, 267).

**Combinations.**—Dissolved in  $H_2O$ , and evaporated, yields long white needles of  $CdBr_2 \cdot 4H_2O$ ; these are dehydrated at  $200^\circ$   $[CdBr_2 \cdot 4H_2O] = 7,730$  (Thomsen).  $CdBr_2Aq$  and  $KBrAq$  mixed and evaporated yield  $2CdBr_2 \cdot 2KBr \cdot H_2O$ , and on further evaporation  $CdBr_2 \cdot 4KBr$ . The double salts

$2CdBr_2 \cdot 2NaBr \cdot 5H_2O$ , and  $CdBr_2 \cdot BaBr_2 \cdot 4H_2O$ , have also been obtained (v. Hauer, *J. pr.* 64, 477; 69, 121. Croft, *J. pr.* 68, 399).  $CdBr_2$  absorbs  $NH_3$  to form  $CdBr_2 \cdot 4NH_3$ ; all  $NH_3$  is removed by heat. Conc.  $CdBr_2Aq$  saturated with  $NH_3$ , and evaporated, gives crystals of  $CdBr_2 \cdot 2NH_3$  (Croft, *P. M.* [3] 21, 355; Rammeisberg, *A.* 44, 267).

**Cadmium, Chloride of.**  $CdCl_2$ . Mol. w. unknown; probably as represented by formula  $CdCl_2$ .  $[541^\circ]$  (Carnelley, *C. J.* 33, 279).  $(861^\circ-954^\circ)$  (Carnelley a. Williams, *C. J.* 35, 564). S.G.  $^{17^\circ}$  3.655 (Clarke, *Am. S.* No. 4). S.  $(20^\circ)$  140;  $(100^\circ)$  150 (Kremers, *P.* 103, 57; 104, 133;

105, 360). H.F.  $[Cd, Cl^2] = 93,240$ ;  $[Cd, Cl^2, Aq] = 96,250$  (Thomsen).

**Preparation.**—By dissolving  $Cd$  in  $HClAq$  and heating to low redness the crystals of  $CdCl_2 \cdot 2H_2O$  which separate on evaporation.

**Properties and Reactions.**—Pearly, lustrous plates; white powder after exposure to air for some time. S.  $(20^\circ-100^\circ)$  abt. 140 (Kremers, *P.* 103, 57; 104, 133). Insoluble in conc.  $HClAq$ .

**Combinations.**—1. With water to form efflorescent prisms of  $CdCl_2 \cdot 2H_2O$ ;  $[CdCl_2 \cdot 2H_2O] = 2,250$  (Thomsen); best obtained by dissolving  $Cd$ ,  $CdO$ , or  $CdCO_3$  in  $HClAq$ , evaporating, and crystallising. 2. With hydrochloric acid and water to form  $3CdCl_2 \cdot 2HCl \cdot 7H_2O$ ; obtained by passing  $HCl$  into  $CdCl_2Aq$ ; easily decomposed in air with evolution of  $HCl$ ;  $[CdCl_2 \cdot 2HCl \cdot 7H_2O] = 40,200$  (Berthelot, *C. R.* 91, 1024). 3. With ammonia, to form  $CdCl_2 \cdot 6NH_3$ , and  $CdCl_2 \cdot 2NH_3$ .  $CdCl_2 \cdot 6NH_3$  is obtained by passing  $NH_3$  over  $CdCl_2$ , or by passing  $HCl$  into  $CdCl_2Aq$  containing excess of  $NH_3$  until the  $NH_3$  is partly neutralised. Loses 4  $NH_3$  by exposure to air, leaving  $CdCl_2 \cdot 2NH_3$ ; this compound is also produced by exposing to air a solution of  $CdCl_2$  in excess of warm  $NH_3Aq$  (Croft, *P. M.* [3] 24, 55; Schüler, *A.* 87, 34; v. Hauer, *J. pr.* 64, 477; v. also André, *C. R.* 104, 908). 4. With various metallic chlorides to form double salts. These salts have been prepared chiefly by Croft (*P. M.* [3] 21, 55), and v. Hauer (*J. pr.* 63, 432; 64, 477; 66, 176; 69, 121); their crystalline forms, and the thermal conductivities of some of them, have been determined by Grailich (*J.* 1858, 182), and v. Lang (*P.* 135, 29). These double compounds are obtained by evaporating mixed solutions of the two chlorides; the chief are:—

5. With the hydrochlorides of many organic bases to form double salts; e.g. with toluidine  $4(C_6H_5NH_2) \cdot 3CdCl_2 \cdot 11H_2O$  (Williams, *C. C.* 1856, 47; Galletly, *C. C.* 1856, 606).

**Cadmium, Cyanide of.**  $Cd(CN)_2$ . Prepared by evaporating  $KCN$  with  $CdCl_2Aq$  (v. CYANIDES).

**Cadmium, Fluoride of.**  $CdF_2$ . Mol. w. unknown; probably as represented by formula.  $[520^\circ]$  (Carnelley, *C. J.* 33, 280). S.G.  $^{22^\circ}$  5.994 (Clarke, *Am. S.* No. 4). Hard, white, crystalline mass; by evaporating solution of  $CdO$  in  $HFAq$ ; not easily soluble in water; much more soluble in  $HFAq$  (Berzelius, *P.* 1, 26). By dissolving  $CdO$  and oxide of  $Sn$ ,  $Zr$ , or  $Mo$  in  $HFAq$ , and evaporating, the double compounds  $CdF_2 \cdot SnF_2 \cdot 6H_2O$ ,  $2CdF_2 \cdot ZrF_2 \cdot 6H_2O$ , and  $CdF_2 \cdot 2ZrF_2 \cdot 6H_2O$ , were obtained by Marignac (*Ann. M.* [5] 15, 221; *A. Ch.* [3] 60, 257); and the double compound  $CdF_2 \cdot MoO_3 \cdot 6H_2O$  by Delafontaine (*J.* 1867, 236).

**Cadmium, Hydrated oxide of.**  $CdO \cdot H_2O$  v. next article.

**Cadmium, Hydroxide of,  $\text{CdO} \cdot \text{H}_2\text{O}$ .** A white, amorphous solid, obtained by adding KOHAq to a dilute aqueous solution of a Cd salt, washing with warm water, and drying at  $100^\circ\text{--}200^\circ$  (Schaffner, A. 61, 168). According to Nickles (*J. Ph.* [3] 12, 406)  $\text{CdO} \cdot \text{H}_2\text{O}$  is obtained in crystals by keeping Cd in contact with Fe in  $\text{NH}_4\text{Aq}$ . De Schulten (*C. R.* 102, 72) describes the formation of hexagonal crystals of  $\text{CdO} \cdot \text{H}_2\text{O}$ , S.G.  $4.79$ , by dissolving 10 grams  $\text{CdI}_2$  in 150 c.c.  $\text{H}_2\text{O}$  mixed with 360 grams KOH containing 13 p.c.  $\text{H}_2\text{O}$ , heating till all is dissolved, and cooling. Thomsen gives the thermal value  $[\text{CdO} \cdot \text{H}_2\text{O}] = 65,680$ ; and the following values for the heat of neutralisation of solid  $\text{CdO} \cdot \text{H}_2\text{O}$  (*Th.* 3, 285):

Q	[M,QAq]	M = $\text{CdO} \cdot \text{H}_2\text{O}$
$\text{H}_2\text{SO}_4$	24,200	
$\text{H}_2\text{N}_2\text{O}_6$	20,620	
$\text{H}_2\text{S}_2\text{O}_7$	20,360	
$\text{H}_2\text{Cl}_2$	20,290	
$\text{H}_2\text{Br}_2$	21,560	
$\text{H}_2\text{I}_2$	24,210	

The quantity of heat produced with the three haloid acids increases as the atomic weight of the halogen increases; in this respect  $\text{CdO} \cdot \text{H}_2\text{O}$  is analogous to the corresponding compounds of Hg and Pb, and differs from those of Ba, Ca, Sr, and Mg.  $\text{CdO} \cdot \text{H}_2\text{O}$  loses  $\text{H}_2\text{O}$  at  $300^\circ$  (H. Rose, P. 20, 152);  $\text{CdO}$  is not hydrated by contact with  $\text{H}_2\text{O}$ ; according to the thermal values given by Thomsen (*Th.* 3, 285; and P. 143, 354 a. 497) the reaction  $\text{CdO} + \text{H}_2\text{O} = \text{CdO} \cdot \text{H}_2\text{O}$  would require the expenditure of about 10,000 units of heat.

**Cadmium, Iodide of,  $\text{CdI}_2$ .** Mol. w. unknown, but probably as represented by the formula.  $[401^\circ]$  (Carnelley, C. J. 33, 278).  $(708^\circ\text{--}719^\circ)$ , with decomposition (Carnelley a. Williams, C. J. 37, 126). S.G.  $\frac{4.81}{4}$  5.644, and 4.626 (v. Preparation a. Properties). H.F.  $[\text{CdI}_2] = 48,830$ ;  $[\text{CdI}_2\text{Aq}] = 47,870$  (Thomsen).  $V_2 = V_0$  ( $1 + 600087480$ ),  $\epsilon$  not greater than  $40^\circ$  (Fizeau, C. R. 61, 314). S. ( $20^\circ$ ) 92.6; ( $60^\circ$ ) 107.6; ( $100^\circ$ ) 133.3 (Kremers, P. 103, 5; 104, 133; 111, 60).

**Preparation and Properties.** 1. By heating together Cd and I, in the ratio Cd:I, in absence of air.—2. By digesting together Cd and I under water (Stromeyer, S. 22, 362).—3. By evaporating a solution of 20 parts KI and 15 parts  $\text{CdSO}_4$  to dryness, dissolving in alcohol, and crystallising (Vogel, N. R. P. 12, 393).—4. By dissolving  $\text{CdCO}_3$  in  $\text{HIAq}$ , decolorising by addition of clippings of Cd, and crystallising (Clarke, Am. 5, No. 4).—5. By dissolving Cd in  $\text{HIAq}$ , evaporating, and crystallising (Clarke, Lc.). According to Clarke (Lc.)  $\text{CdI}_2$  exists in two forms; the normal salt is white, is unchanged by heating to  $250^\circ$ , and has S.G. 5.644; the other salt is brownish, loses weight even at  $40^\circ$ , and has S.G. 4.626. The conditions under which the less stable salt is formed have not yet been exactly determined; Clarke obtained it twice by the action of  $\text{HIAq}$  on Cd and on  $\text{CdCO}_3$ . The S.G. of the less stable salt increases by heating to  $50^\circ$  for some time. If the formula-weight  $\text{CdI}_2$  is divided by the S.G., the results are, for the stabler salt 61.8, and for the less stable salt 79.2; now S.V.S. of Cd + S.V.S. of  $\text{I}_2 = 64.3$  (Clarke, Lc.).

**Combinations.**—1. With ammonia to form  $\text{CdI}_2 \cdot 6\text{NH}_3$  and  $\text{CdI}_2 \cdot 2\text{NH}_3$ ; obtained as the corresponding  $\text{CdCl}_2$  compounds (q. v.): both are decomposed by  $\text{H}_2\text{O}$  with p.p.n. of  $\text{CdO} \cdot \text{H}_2\text{O}$  (Rammelsberg, P. 48, 153).—2. With some metallic iodides to form double salts; Croft (*J. pr.* 68, 399) described  $\text{CdI}_2 \cdot 2\text{KI} \cdot 2\text{H}_2\text{O}$  (aqueous solution of this salt pps. most of the organic bases from plants; Marmé, N. R. P. 16, 306);  $\text{CdI}_2 \cdot 2\text{NH}_4\text{I} \cdot 2\text{H}_2\text{O}$ ;  $\text{CdI}_2 \cdot 2\text{NaI} \cdot 6\text{H}_2\text{O}$ ;  $\text{CdI}_2 \cdot \text{BaI}_2 \cdot 5\text{H}_2\text{O}$ ; and  $\text{CdI}_2 \cdot \text{SrI}_2 \cdot 8\text{H}_2\text{O}$ . Clarke (Am. 5, No. 4) obtained  $\text{CdI}_2 \cdot 3\text{HgI}_2$  as gold-coloured plates.

**Cadmium, Oxide of,  $\text{CdO}$ .** Mol. w. unknown. S.G. (amorphous) 6.95, (crystalline) 8.11 (Stromeyer, S. 22, 362; Werther, J. pr. 55, 188; Schüler, A. 87, 34; Sidot, C. R. 69, 201; Follenius, Fr. 13, 279). H.F.  $[\text{CdO}] = 75,500$  (calculated from data given by Thomsen, Th. 3, 285; P. 143, 354 a. 497).

**Preparation.**—As a dark-brown, amorphous, infusible, powder, by burning Cd in air or O; or by strongly heating  $\text{CdO} \cdot \text{H}_2\text{O}$ , or  $\text{CdCO}_3$ . As black-brown very small octahedra (or other forms of the monometric system), by strongly heating  $\text{Cd}_2\text{XO}_3$ , or  $\text{CdSO}_4$  (Werther, Lc.; Schüler, Lc.; Herapath, B. J. 3, 109).

**Properties &c.**—Reduced to Cd by heating with C. At red heat Cl forms  $\text{CdCl}_2$ . Readily combines with  $\text{CO}_2$  forming  $\text{CdCO}_3$ . Dissolves in aqueous acid with production of Cl salts. Thomsen (P. 143, 354 a. 497) gives the thermal values,  $[\text{CdO} \cdot \text{H}_2\text{SO}_4\text{Aq}] = 14,240$  for crystalline  $\text{CdO}$ , and 14,510 for amorphous  $\text{CdO}$ .

Marchand (P. 38, 145) supposed that a lower oxide than  $\text{CdO}$  was formed when  $\text{CdCO}_3$  was heated; but Vogel's experiments (*J.* 1855. 390) seem to prove that the substance was a mixture, in varying proportions, of  $\text{CdO}$  and Cd.

By the action of  $\text{H}_2\text{O}_2\text{Aq}$  (about 3 p.c.  $\text{H}_2\text{O}_2$ ) on moist  $\text{CdO} \cdot \text{H}_2\text{O}$ , Haas (B. 17, 2219) obtained an oxide of Cd containing more O than  $\text{CdO}$ . Analyses gave results agreeing fairly with the formula  $\text{Cd}_2\text{O}_3$ , in one case with  $\text{Cd}_2\text{O}_4$ . These results were confirmed by Bailey (C. J. 49, 484) who obtained  $\text{Cd}_2\text{O}_3$  by the action of  $\text{H}_2\text{O}_2\text{Aq}$  on  $\text{CdSO}_4\text{Aq}$  followed by addition of  $\text{NH}_4\text{Aq}$ . The pp. obtained by these methods may have been a mixture, or possibly a loose compound, of  $\text{CdO}$  and  $\text{Cd}_2\text{O}_3$  (v. Haas, Lc. 2255).

**Cadmium, Phosphides of,  $\text{Cd}$  and  $\text{P}$  are said to combine when heated together to form a grey, slightly metal-like, mass, which burns in air to phosphates, and dissolves in  $\text{HClAq}$  with evolution of  $\text{PH}_3$  (Stromeyer, S. 22, 362). According to B. Renault (C. R. 76, 283) when P vapour is passed over hot Cd, two phosphides are formed,  $\text{Cd}_3\text{P}_2$  and  $\text{Cd}_2\text{P}$ . Oppenheim (B. 5, 979) describes  $\text{Cd}_3\text{P}_2$  as a grey, metal-like, crystalline substance, produced by heating  $\text{CdO}$  with  $\text{KOHAq}$  and P, and heating in H.**

**Cadmium, Salts of.** Compounds obtained by replacing the H of acids by Cd. The Cd salts form one series  $\text{CdX}_2$ , when  $\text{X} = \text{Cl}$ ,  $(\text{NO}_3)$ ,  $(\text{ClO}_3)$ ,  $\text{SO}_4$ ,  $\text{CO}_3$ ,  $\text{HPO}_4$ , &c. The V.D. of one salt,  $\text{CdBr}_2$ , has not been determined; from this result, and from the similarities between the salts of Cd and Zn, it is probable that the gaseous molecules of the haloid Cd salts are

correctly represented by the formula  $CdX$ , where  $X = F, Cl, Br, \text{ or } I$ . The greater number of the salts of Cd are soluble in water; the aqueous solutions reddened blue litmus paper; they are poisonous. The haloid salts are not decomposed by heat; salts of volatilisable acids give CdO when strongly heated. Many Cd salts are isomorphous with corresponding salts of Zn; some, especially more complex double salts, are isomorphous with corresponding salts of Mg, Ni, Co, and Zn. A great many double salts containing  $CdX_2$  ( $X = Cl, Br, I$ ) are known; but few basic salts of Cd have been prepared. The principal Cd salts are borate; bromate; carbonates, ~~the~~ chlorate, perchlorate; chromate; cyanates, ~~and~~ iodate, periodate; molybdate; nitrates, nitrites; phosphates, phosphite; selenates, selenite; sulphates, sulphite, &c.; tungstate; vanadate; *v.* BORATES, CARBONATES, &c.

**Cadmium, Selenide of.**  $CdSe$ . Golden yellow, metal-like, crystalline, mass; by heating Cd in Se vapour; S.G. 8.79 (Stromeyer, *S.* 22, 362). The same body is said to be formed as a dark-brown pp. by passing  $H_2Se$  into solution of a Cd salt (Vigier, *Lit.* 1861, 5; Renault, *C. R.* 76, 283).

**Cadmium, Silicofluoride of.**  $CdSiF_6$ . Long, columnar, deliquescent crystals, obtained by action of  $H_2SiF_6$  Aq on CdO (Berzelius, *P.* 1, 26).

**Cadmium, Sulphide of.**  $CdS$ . Occurs native in hexagonal prisms ( $ac = 1:81257$ ) as *Greenockite*. Obtained as an amorphous yellow solid, by repeatedly heating to dull redness  $CdSO_4$  in  $H_2S$  (*v.* Hauer, *J. pr.* 72, 338); by passing  $H_2S$  into a slightly acid solution of a Cd salt; by heating Cd with  $SO_4$  Aq (Geitner, *A.* 87, 34; Fordos & Gélis, *A.* 50, 260; Schweitzer, *C. N.* 23, 293). Obtained also in crystalline form by fusing the amorphous  $CdS$  with  $K_2CO_3$  and S (Schüler, *A.* 87, 34); by heating  $CdCl_2$  in  $H_2S$ ; or by melting together  $CdSO_4$ ,  $CaF_2$ , and  $NaS$  (Troost & Deville, *C. R.* 52, 920).  $CdS$  is also produced in crystals, but in small quantity, by passing S vapour over strongly heated CdO, or Cd (Follenius, *Fr.* 13, 411; Sidot, *C. R.* 62, 999). Crystalline  $CdS$  is non-volatile at any temperature; it dissolves easily in boiling conc.  $HCl$  Aq, or dilute  $H_2SO_4$  Aq (Follenius, *l.c.*; Hofmann, *A.* 115, 286); S.G. 4.5, when melted 4.6. Schiff (*A.* 115, 74) described  $CdS$  as a yellow powder obtained by the action of  $K_2S_2O_8$  Aq on a neutral Cd salt in solution; according to Follenius (*Fr.* 13, 411) this yellow solid is a mixture of  $CdS$  and S.

**Cadmium, Sulphocyanide of.**  $Cd(CNS)_2$ . Obtained by action of  $HCN$  SAq on  $CdCO_3$ ; *v.* SULPHOCYANIDES, under CYANIDES.

**Cadmium, Telluride of.**  $CdTe$ . Black crystals, S.G. 6.20, by heating Cd with Te, and subliming the product in  $H$  (Margottet, *C. R.* 85, 1142).

**CADMIUM ETHIDE**  $CdEt_2$ . Obtained in impure condition from  $EtI$  and Cd. Takes fire in air (Wanklyn, *C. J.* 9, 193; Sonnenschein, *J. pr.* 67, 169).

**CAESIUM.** Cs. At. w. 132.7. [ $26^\circ - 27^\circ$ ] (Setterberg, *A.* 211, 100). S.G.  $1.88$  (Setterberg, *l.c.*). S.V.S. 70.7. Discovered by Bunsen and Kirchhoff as chloride in the water of a mineral spring at Dürkheim (*P.* 113, 342).

Vol. I.

Name given because element characterised by two sky-blue (*caesius*) lines in the spectrum.

**Occurrence.**—Never free. Salts very widely distributed, but in very small quantities, along with Rb, chiefly as chloride and oxide; in many minerals and mineral waters, in sea water and sea weed, in residues from saltpetre refining, in ash of tobacco, tea, coffee, and oak wood, &c. (*v.* especially Laspeyres, *A.* 131, 349; 133, 326; also Smith, *Am. S.* [2] 49, 335; Erdmann, *J. pr.* 86, 377; Grandeaun, *C. R.* 53, 1100; Lonstadt, *C. N.* 22, 25 a. 44). The rare mineral *Polluc*, from Elba, according to analyses by Pisani, contains 84 p.c. of oxide combined with silica, and is free from Irb (*A.* 132, 31).

**Preparation.**—1. The mother liquor, obtained by repeatedly evaporating the water of the mineral spring at Nanheim, and separating from the crystals which form, contains nearly  $\frac{1}{2}$  p.c.  $CsCl$ . Fe, Al, and the alkaline earth metals, are removed in the usual way; the liquid is evaporated, and heated to volatilise ammonium salts added in the preceding processes; the residue is dissolved in water and the Cs and Rb are ppd. as double chlorides of Cs, or Rb, and Pt, by addition of  $PtCl_4$  Aq. The pp. is boiled in a very little water, and allowed to settle, the water is poured off while still hot; this process is repeated about 20 times, when the pp. will be quite free from  $K_2PtCl_6$  and will consist of  $Cs_2PtCl_6$  mixed with  $Rb_2PtCl_6$ . The pp. is now reduced in  $H$ ,  $CsCl$  and  $RbCl$  are dissolved out in boiling  $H_2O$  (Böttger, *J. pr.* 91, 126). The mixed chlorides are converted into sulphates, these are dissolved in  $H_2O$ ,  $BaO$  Aq is added,  $BaSO_4$  is removed by filtration, and the filtrate is evaporated to dryness in a silver dish after addition of  $(NH_4)_2CO_3$ ; the residue is dried, dissolved in water,  $BaCO_3$  removed by filtration, and twice as much  $H_2C_2H_3O_6$  is added as is required to neutralise the solution of  $Cs_2CO_3$  and  $Rb_2CO_3$ ; the liquid is evaporated at  $100^\circ$  and crystallised; the pp. consists of  $CsH_2C_2H_3O_6$  mixed with  $RbH_2C_2H_3O_6$ . As the latter salt requires 8 times as much  $H_2O$  as the former for solution, the two salts may be completely separated by fractional precipitation; this process is continued until the crystals of Cs tartrate do not show a trace of Rb in the spectroscopic (Bunsen, *P.* 119, 1; Allen, *P. M.* [4] 25, 189). By heating the tartrate, and dissolving the residue in  $H_2SO_4$  Aq, and crystallising,  $Cs_2SO_4$  may be prepared; this is dissolved in  $H_2O$ , decomposed by  $BaO$  Aq, and the solution is filtered and evaporated to dryness in a silver dish, when  $CsOH$  is obtained. The  $CsOH$  is dissolved in absolute alcohol, and dry  $HCN$  is passed into this solution:  $CsCN$  is thus obtained as a white solid (Setterberg, *A.* 211, 100). A mixture of 4 parts  $CsCN$  and 1 part  $Ba(CN)_2$  is heated just to melting in a porcelain crucible, and an electric current from 2 or 3 Bunsen cells is passed into the molten mass, in the manner described by Bunsen (*P.* 155, 633). The contents of the crucible are then warmed under petroleum when the metallic Cs melts into globules (Setterberg, *A.* 211, 100).—2. The mixed chlorides of Cs and Rb, obtained as in 1, are converted into sulphates, and then into alums by adding  $Al_2(SO_4)_3$  Aq and evaporating. Rb alum is 4 times more soluble than Cs alum; Cs alum

II II

may be obtained quite free from Rb by a few crystallisations. The Cs alum is dissolved in hot  $H_2O$ , and pptd. by  $NH_4Aq$ , the liquid is filtered from  $Al_2O_3$ , evaporated to dryness in a Pt dish and strongly heated to remove  $(NH_4)_2SO_4$ ; the residue is dissolved in  $H_2O$ , and  $BaCl_2Aq$  is added so long as a pp. of  $BaSO_4$  forms; the pp. is filtered off,  $NH_4Aq$  and  $(NH_4)_2CO_3Aq$  are added to the filtrate, the liquid is kept warm for some time, and is then filtered from any  $BaCO_3$  which has formed; the filtrate is evaporated to dryness, and heated to fusion; solution in  $H_2O$ , treatment with  $NH_4Aq$  and  $(NH_4)_2CO_3$ , evaporation, and fusion are repeated; finally  $CsCl$  is obtained by dissolving the fused mass in  $H_2O$ , and crystallising (Godeffroy, *A.* 181, 176; Redtenbacher, *J.* pr. 95, 148). This is converted into  $Cs_2SO_4$ , and then into  $CsOH$  which is treated as described in 1.—3. *Lepidolite* (a silicate of Al), from Hebron, in Maine, U.S.A., contains about .4 p.c. Cs oxide and .2 p.c. Rb oxide. The powdered mineral is well mixed with 2 parts freshly slaked  $CaO$ , and very strongly heated for some time; the mass is powdered, half its weight of conc.  $H_2SO_4Aq$  is added, followed by water; the whole is boiled, filtered, and evaporated to dryness; the residue is dissolved in water, filtered from  $CaSO_4$ , and evaporated until the alums of K, Cs, and Rb crystallise out. About 4 kilos. of the crude mixed alums was prepared by Setterberg (*A.* 211, 100), and dissolved in hot water, so that the solution had  $S.G. = 20^\circ$  Beaumé; this was cooled slowly to  $45^\circ$ , when the Cs and Rb alums were deposited, as they are insoluble in cold conc. potash alum solution. The alums were dissolved in a little hot water and again cooled, and then solution and crystallisation was continued until the crystals were free from potash. Cs alum is 4 times less soluble in  $H_2O$  than Rb alum, and is insoluble in a saturated solution of the latter; the mixed alums were dissolved in a little hot water, and allowed to cool, when Cs alum separated with a little Rb alum; this process was repeated until pure Cs alum was obtained. The alum was dissolved in hot water, enough  $BaOAq$  added to ppt.  $Al_2O_3$ , and all the  $H_2SO_4$ , the solution was filtered off and evaporated to dryness; the  $CsOH$  thus obtained was dissolved in absolute alcohol, and  $CsCN$  was prepared; the  $CsCN$  was then electrolysed as described in 1. (For other processes for preparing pure salts of Cs v. Godeffroy, *B.* 7, 241; Cossa, *B.* 11, 812; Stolba, *D. P. J.* 197, 336; 198, 225; Sharples, *Am. Ch.* 3, 453. For an account of attempts to prepare the metal by various methods similar to those used for preparing Rb, v. Smith, *Am. Ch.* 6, 106.)

**Properties.**—Silver white, soft, ductile, metal; oxidises rapidly with production of heat and light in air; decomposes  $H_2O$  at ordinary temperature with inflammation of H produced. Melts  $26^\circ-27^\circ$ ;  $S.G.$  at  $15^\circ$  1.88 (Setterberg, *A.* 211, 100). Spectrum characterised by two lines in the blue,  $Cs_2 = 4560$ ,  $Cs_1 = 4597$ ; .00005 mgrm. Cs may be detected by the spectroscope; .003  $CsCl$  may be detected in presence of 300-400 parts of  $KCl$  or  $NaCl$ ; .001  $CsCl$  in presence of 1500  $LiCl$  (Bunsen, *Lc.*). The atomic weight of Cs has been determined (1) by determination

of V.D. of  $CsCl$ , and analyses of the same salt; by Bunsen (*P.* 113, 853; 119, 4), by Johnson a. Allen (*Am. S.* 35, 94), and by Godeffroy (*A.* 181, 185); (2) by comparing the reactions of Cs compounds with compounds of Li, K, Na, and Rb. One gaseous compound of Cs has been obtained; the S.I.L. of the metal has not been determined. Cs is positive to all other elements (v. ALKALI METALS).

**Combinations.**—No compounds of Cs have as yet been prepared directly from the metal. When conc.  $CsClAq$  is electrolysed with Pt as the +, and Hg as the - electrode, an amalgam of Cs and Hg is formed, and solidifies to a white crystalline mass; the Cs in this amalgam very quickly oxidises to  $CsOH$ .

**Detection and Estimation.**—Most of the salts of Cs are easily soluble in water. Cs salts may be detected by the comparative insolubility in  $H_2O$  of  $Cs_2PtCl_6$  (v. Preparation, No. 1), and by the spectroscope. There is no satisfactory method for separating and estimating Cs salts; the pp. by  $PtCl_4$  contains  $Rb_2PtCl_6$  and a little  $K_2PtCl_6$ ; by repeating the ppn. the pp. may be obtained almost free from  $K_2PtCl_6$ ; the pp. is then reduced in H, the  $CsCl$  and  $RbCl$  dissolved out, the liquid evaporated and the residue weighed; the Cl is then estimated and the quantity of  $CsCl$  is calculated.

**Cæsium chloride  $CsCl$ .** Mol. w. 168.07 (Scott, *Pr. E.* 1888). For preparation a **Cæstum**, Preparation, No. 2. Small, white, cubes; not deliquescent when pure; partially decomposed by melting in air, residue is alkaline. Melts at low red heat, and volatilises at a higher temperature. Easily soluble in  $H_2O$  and alcohol.  $CsCl$  forms several double compounds, insoluble in conc.  $HClAq$ , with other metallic chlorides; they are obtained by adding  $CsCl$  in conc.  $HClAq$  to a solution of the other chloride also in conc.  $HClAq$ . The following are known:  $2CsCl.CdCl_2$ ,  $2CsCl.HgCl_2$ ,  $2CsCl.ZnCl_2$ ,  $2CsCl.CuCl_2$ ,  $2CsCl.MnCl_2$ ,  $2CsCl.NiCl_2$ ,  $2CsCl.PdCl_2$ ,  $6CsCl.Fe_2Cl_3$ ,  $6CsCl.BiCl_3$ ,  $6CsCl.SbCl_3$ ,  $CsCl.AuCl_3$ ,  $2CsCl.PtCl_4$  (Stolba, *D. P. J.* 198, 225; Godeffroy, *B.* 7, 375; 8, 9);  $2CsCl.PtCl_4$ ,  $S. (0^\circ) .024, (100^\circ) .377$ . When molten  $CsCl$  is electrolysed in an atmosphere free from O, a small blue mass is obtained which is dissolved by  $H_2O$  with evolution of H; probably this is due to formation of a subchloride.

**Cæsium cyanide  $CsCN$ .** Prepared by the action of dry HCN on  $CsOH$  dissolved in absolute alcohol; v. CYANIDES.

**Cæsium hydroxide  $CsOH$ .** Mol. w. unknown. Prepared (as described under CÆSIUM, Preparation, No. 1) by decomposing  $Cs_2SO_4Aq$  by  $BaOAq$ , filtering off  $BaSO_4$ , and evaporating to dryness in a silver dish. Grey-white solid, melting below redness; undecomposed by heat; deliquesces in air, with production of much heat, to form strongly alkaline  $CsOHaq$ .

**Cæsium oxide.** An oxide of Cs has not yet been prepared.

**Cæsium, Salts of.** Compounds obtained by replacing H of acids by Cs.  $CsOHaq$  acts as a very strong base. The salts belong to one series  $CsX$  where  $X = Cl, NO_3, SO_4, CO_3$ , &c.; the formulæ are established from the vapour

density of  $\text{CsCl}$ , (Scott, *Pr. E.* 1888), and also by comparing the salts with those of the other alkali metals. The salts of Cs are very similar to those of Rb; they are well marked, stable, compounds; no basic salts are known; so far as investigation has gone the Cs salts show a marked tendency to form double salts. Most of the salts of Cs are soluble in water; the solutions are ppd. by  $\text{PtCl}_4\text{Aq}$  (yellow), by  $\text{H}_2\text{C}_2\text{H}_3\text{O}_4\text{Aq}$  (white), by  $\text{HClO}_4\text{Aq}$  (white), and by silicotungstic acid (white). The chief salts are carbonates, nitrate, selenates, silicotungstate, sulphates, tartrate (v. CARBONATES, &c.).

M. M. P. M.

**CAFFEIC ACID**  $\text{C}_8\text{H}_6\text{O}_4$ , i.e.  $[\text{4:3}] \text{C}_6\text{H}_3(\text{OH})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . *Di-oxy-cinnamic acid*. *Di-oxy-phenyl-acrylic acid*.

**Formation**.—1. By boiling caffeotannic acid with aqueous KOH (Hlasiwetz, *A.* 142, 221).—2. From its acetyl derivative.—3. Powdered cuprea bark is extracted with ether followed by alcohol; the residue is boiled with aqueous KOH,  $\text{H}_2\text{SO}_4$  is added, and the liquid filtered while hot. The filtrate, when cold, is exhausted with ether, and the ethereal solution, after decolorising with animal charcoal, is set aside to crystallise (G. Körner, *Ph.* [3] 13, 246).—4. From hemlock (in which it is combined with conhydrine?) (Hofmann, *B.* 17, 1922).

**Properties**.—Yellow monoclinic tables (containing 4aq), v. s. sol. alcohol. The aqueous solution is turned green by  $\text{FeCl}_3$ , on adding  $\text{Na}_2\text{CO}_3$  it then changes to blue and violet. It does not reduce Fehling's solution but reduces warm ammoniacal  $\text{AgNO}_3$ . Its solution in  $\text{KOH}$  turns brown in air.

**Reactions**.—1. Dry distillation gives pyrocatechin.—2. Potash fusion forms protocatechuic acid.—3. Sodium amalgam reduces it to di-oxy-phenyl-propionic acid.

**Salts**.— $\text{CaA}'_2$  3aq.  $\text{SrA}'_2$  4aq.  $\text{BaA}'_2$  4aq.  $\text{Ba}_2(\text{C}_8\text{H}_6\text{O}_4)_2 \cdot 9\text{H}_2\text{O}$ — $\text{Pb}_2(\text{C}_8\text{H}_6\text{O}_4)_2 \cdot 2\text{aq}$ .

**Mono-methyl derivative v. FERULIC ACID**.

**Di-methyl derivative**  
 $\text{C}_8\text{H}_8(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [180°]. Formed by saponifying the ether or by heating caffeic or ferulic acid with MeI and KOH. White needles. Sol. alcohol and ether, nearly insol. water. On oxidation with  $\text{KMnO}_4$  it produces veratric acid. Methyl ether A'Me. [64°]. Prisms. Prepared by methylation of isoferulic acid (Tiemann a. Will, *B.* 11, 651; 14, 959).

**Methylene ether**  
 $\text{CH}_2<\text{O}>\text{C}_8\text{H}_8\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [232°]. Formed by boiling piperonal  $\text{CH}_3\text{O}_2\text{C}_6\text{H}_4\text{CHO}$  with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  (Lorenz, *B.* 13, 757). Minute crystals (from dilute alcohol). Conc.  $\text{H}_2\text{SO}_4$  forms a brick-red solution.— $\text{AgA}'$ .

**Acetyl-methyl derivatives v. ACETYL-FERULIC ACID**.

**Di-acetyl derivative**  
 $\text{C}_8\text{H}_8(\text{OAc})_2\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [191°]. From caffeic acid and  $\text{Ac}_2\text{O}$  or by heating protocatechuic aldehyde (2 pts.) with  $\text{NaOAc}$  (2 pts.) and  $\text{Ac}_2\text{O}$  (6 pts.). Slender needles. V. sl. sol. water, v. sol. alcohol and ether (Tiemann a. Nagai, *B.* 11, 659).

**Hydro-caffeic acid v. DI-OXY-PHENYL-PROPIONIC ACID**.

**CAFFEIDINE**  $\text{C}_7\text{H}_{12}\text{N}_2\text{O}$ . Formed, together with methylamine,  $\text{CO}_2$ , and  $\text{NH}_3$ , by boiling caffeine with conc. baryta-water (Strecker, *A.* 123, 360; 157, 1; *C. R.* 52, 1269; Schmidt, *B.* 14, 816; Schultzen, *Z.* 1867, 616). Alkaline liquid. Sol. wat. r. alcohol, and chloroform, sl. sol. ether. Long boiling with baryta-water gives methyl-amido-acetic acid, formic acid,  $\text{CO}_2$ , and  $\text{NH}_3$ . Chromic acid oxidises it to di-methyl-~~amide~~, methylamine,  $\text{CO}_2$ , and  $\text{NH}_3$ . (Maly a. Andreasch, *M.* 4, 381). EtI forms  $\text{C}_7\text{H}_{11}\text{EtN}_2\text{O}$ .

**Salts**.— $\text{B'HCl}$ .— $\text{B'H}_2\text{PtCl}_4$  4aq.

**CAFFEIDINE CARBOXYLIC ACID**

$\text{C}_8\text{H}_{12}\text{N}_2\text{O}_2$ . Prepared by the gradual solution of caffeine in dilut.  $\text{NaOH}$ aq; this solution is neutralised with  $\text{HOAc}$  and the eq. salt ppd. with  $\text{Cu}(\text{OAc})_2$  (Maly a. Andreasch, *M.* 4, 369). Very soluble crystalline mass; its aqueous solution on boiling gives off  $\text{CO}_2$  and leaves caffeidine.

**Salts**.— $\text{KA}'$ : golden syrup.  $\text{HgA}'_2 \cdot 2\text{HgCl}_2$ : bulky pp.  $\text{CuA}'_2$ : minute crystalline granules.— $\text{CaA}'_2$ .— $\text{ZnA}'_2$ .— $\text{CdA}'_2$ .— $\text{MgA}'_2$ .

**CAFFEINE**  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ . *Theine*. [230.5°]. *S. G.* 1.23. *S.* 1.35 at 16°; 45.6 at 65° (Commaille, *C. R.* 81, 817). *S.* (alcohol) .61 at 16°; .312 at 78°. *S.* (ether) .014 at 16°. *S.* (CS<sub>2</sub>) .06 at 16°. *S.* (chloroform) 13 at 16°.

**Occurrence**.—1. In coffee berries and leaves (Runge, *Materialien zur Phytologie*, 1820; Stenhouse, *P. M.* [4] 7, 21; Pfaff a. Liebig, *A.* 1, 17). Coffee berries contain from 1 to 1.28 p.c. caffeine; roasted coffee about 1.3 p.c. (Paul a. Cownley, *Ph.* [3] 17, 565; cf. Stenhouse a. Campbell, *C. J.* 9, 33; *A.* 89, 246).—2. In tea leaves (Oudry, *Mag. Pharm.* 1849; Jobst, *A.* 25, 63; Mulder, *P.* 43, 160). Tea contains 2 to 4 p.c.—3. In guarana, the dried pulp of *Paulinia sorbilis* (Martius, *A.* 36, 93). Guarana contains about 5 p.c. of caffeine.—4. In Maté or Paraguay tea the leaves and twigs of *Ilex Paraguayensis* (Stenhouse, *P. M.* [3] 23, 426). 5. In the seeds of the Kola tree (*Cola acuminata*) of West Central Africa, to the amount of 2.13 p.c. of the dried seed (Atfield, *Ph.* [2] 6, 457).—6. Present to a small extent in cocoa (E. Schmidt, *A.* 217, 306).

**Formation**. By heating silver theobromine with MeI for 20 hours at 160°; caffeine is thus shown to be methyl-theobromine (Strecker, *A.* 118, 151; E. Schmidt, *A.* 217, 282).

**Preparation**.—1. Tea or coffee is exhausted with boiling water; tannin is ppd. by lead subacetate; the filtrate is freed from lead by  $\text{H}_2\text{S}$  and evaporated to crystallisation (Péligot, *A. Ch.* [3] 11, 129).—2. Raw ground coffee (5 pts.) is mixed with moist lime (2 pts.) and extracted with alcohol, chloroform, or benzene, from which the caffeine crystallises on evaporation (Versmann, *Ar. Ph.* [2] 68, 148; Vogel, *C. C.* 1858, 367; Payer, *A. Ch.* [3] 26, 108; Paul a. Cownley, *Ph.* [3] 17, 565).—3. Tea or coffee is boiled with water and either the whole, or else the filtrate, is evaporated to a syrup, mixed with slaked lime and extracted with chloroform (Hubert, *Pflüger's Archiv*, 5, 589; Cazeneuve a. Caillol, *Bl.* [2] 27, 199).—4. By sublimation from tea (Heinyusius, *J. pr.* 49, 317).—5. A decoction of tea is evaporated with  $\text{PbO}$  to a syrup,  $\text{K}_2\text{CO}_3$  is added, and caffeine extracted by alcohol (Grosschoff, *J.* 1866, 470).

**Properties**.—Mass of slender silky needles (containing 4aq); begins to sublime at 79°

(Blyth). Sl. sol. cold water and alcohol, v. sl. sol. ether. The crystals from alcohol and ether are anhydrous. Weak base; the salts being decomposed by water; does not affect red litmus. Tastes bitter. Produces tetanus and rigor in the voluntary muscles of frogs (Aubert; Brunton, *A. Cash*, *Pr.* 42, 238). In men it increases the heart's action, excites the nervous system, and diminishes metabolism (?) (Lehmann, *A.* 87, 205). Caffeine gives a yellow pp. with phosphomolybdic acid.

**Estimation.**—The various methods of preparation may also be used for estimation (Stenhouse, *A.* 102, 126; Lieventhal, *C. C.* 1872, 631; Weyrick, *Fr.* 12, 181; Püligot, *Rep. Pharm.* 82, 340; Claus, *J.* 1863, 708; Zöller, *J.* 1871, 818; Mulder, *J. pr.* 15, 280; Commaille, *Bl.* [2] 25, 261; Paul a. Cownley, *Ph.* [3] 17, 565).

**Colour Test.**—Evaporate with chlorine-water on platinum-foil. A yellowish residue is left, which on further heating becomes red, and is turned purple by ammonia (Schwarzenbach, *J.* 1861, 871; 1865, 730). Xanthine, theobromine and uric acid also give this test. Caffeine evaporated with conc.  $\text{HNO}_3$  gives a yellow residue (amalic acid) which is also turned purple (murexide) by ammonia (Rochleder, *A.* 69, 120).

**Reactions.**—1. Gaseous chlorine or  $\text{HCl}$  and  $\text{KClO}_4$  give in the first place di-methyl-alloxan and methyl-urea (E. Fischer, *A.* 215, 257):  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 + \text{O}_2 + 2\text{H}_2\text{O} = \text{C}_6\text{H}_8\text{N}_4\text{O}_2 + \text{C}_2\text{H}_4\text{N}_2\text{O}$ . Part of the di-methyl-alloxan becomes amalic acid. Chloro-caffeine, methylamine, and cyanogen chloride are also formed, and, if the reaction is prolonged, di-methyl-parabanic acid (cholestrophane). Bromine and water at  $100^\circ$  act similarly (Maly a. Hinterberger, *M.* 3, 85).—2. Cold  $\text{HNO}_3$  attacks it slowly, giving off  $\text{CO}_2$  (1 vol.) and  $\text{N}_2\text{O}$  (about 2 vols.) (Franchimont, *R. T. C.* 6, 223).—3. Hot dilute  $\text{HNO}_3$  gives di-methyl-parabanic acid (Cannhouse, *A.* 45, 366; 46, 227; Rochleder, *A.* 69, 120; 71, 1).—3. Chromic acid gives di-methyl-parabanic acid,  $\text{NH}_3$ , methylamine, and  $\text{CO}_2$  (Maly a. Hinterberger, *M.* 2, 87).—4. Boiling baryta water splits up caffeine into caffeidine and  $\text{CO}_2$ ; the caffeidine then breaks up into  $\text{CO}_2$ ,  $\text{NH}_3$ , methylamine, formic acid, and methyl-amido-acetic acid (sarcosine) (Rosengarten a. Strecker, *A.* 157, 1). 5. With conc.  $\text{HCl}$  at  $250^\circ$  it forms ammonia, methylamine, sarcosine, formic acid and  $\text{CO}_2$  (E. Schmidt, *A.* 217, 270). The volume of  $\text{NH}_3$  is that of  $\text{NMeH}_2$  as 1:2. Below  $200^\circ$ ,  $\text{HCl}$  has no action. Hence there are three  $\text{NMe}$  groups in caffeine,  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 + 6\text{H}_2\text{O} = 2\text{CO}_2 + 2\text{NMeH}_2 + \text{NH}_3 + \text{CH}_3\text{CO}_2 + \text{C}_2\text{H}_5\text{NO}_2$ .

**Salts.**—(E. Schmidt, *A.* 217, 282; Herzog, *A.* 26, 344; 29, 171; Biederlann, *Ar. Ph.* [3] 21, 175; Tilden, *O. J.* 18, 99; 19, 145).  $\text{B'HCl}$ — $\text{B'HCl}$  2aq. monoclinic; decomposed by moist air into  $\text{HCl}$  and caffeine.— $\text{B}'2\text{HCl}$ — $\text{B}'4\text{HCl}$ — $\text{B}'_2\text{H}_2\text{tCl}_2$  (at  $100^\circ$ ).— $\text{B}'\text{HAuCl}$  2aq. glittering plates.— $\text{B}'\text{HBr}$  2aq.— $\text{B}'\text{HI}$ — $\text{B}'2\text{HI}$ — $\text{B}'\text{HI}$  1½aq (Tilden).— $\text{B}'\text{HgCl}_2$  [175?]; yellow needles converted by  $\text{NH}_3$  into a greenish-black pp. (Tilden, *Z.* 1866, 350; Ostermayer, *B.* 18, 2298).— $\text{B}'\text{HNO}_3$  aq.— $\text{B}'\text{H}_2\text{SO}_4$ — $\text{B}'\text{H}_2\text{SO}_4$  aq. Formate  $\text{B}'\text{H}_2\text{CO}_2$ —Acetate  $\text{B}'2\text{HOAc}$ —Butyrate  $\text{B}'\text{C}_4\text{H}_7\text{O}_2$ —Isovalerate  $\text{B}'\text{C}_5\text{H}_9\text{O}_2$ —Citrate: prepared by adding a solution of

citric acid (1 pt.) in alcohol (7½ pts.) to one of caffeine (1 pt.) in chloroform (14½ pts.) and evaporating. Semi-crystalline powder, decomposed by most solvents (Lloyd, *Ph.* [3] 11, 760). According to Lanret (*J. Ph.* [5] 6, 591) the last five salts are merely mixtures.—Caffeate  $\text{B}'\text{C}_8\text{H}_7\text{O}_2$  2aq (Ellasiwetz, *A.* 142, 226).

**Combinations.**— $\text{B}'\text{HgCl}_2$  (Nicholson, *A.* 62, 78; Hinterberger, *A.* 82, 316).— $\text{B}'\text{HgCy}$  (Kohl a. Swoboda, *A.* 83, 341).— $\text{B}'\text{AgNO}_3$ .

**Methylo-chloride**  $\text{B}'\text{MeCl}$  aq. At  $200^\circ$  it splits up into  $\text{MeCl}$  and caffeine.—( $\text{B}'\text{MeCl}$ ),  $\text{PtCl}_4$ . Sparingly soluble.

**Methylo-iodide**  $\text{B}'\text{MeI}$  aq (Tilden, *J. pr.* 94, 374; E. Schmidt, *A.* 217, 286; E. Schmitt a. E. Schilling, *A.* 228, 141). From caffeine and  $\text{MeI}$  at  $130^\circ$ . At  $100^\circ$  it loses aq, at  $190^\circ$  it splits up into caffeine and  $\text{MeI}$ . Triclinic:  $\alpha:b:c = 6962:1:4161$ ;  $a = 91^\circ 24'$ ;  $\beta = 74^\circ$ ;  $\gamma = 88^\circ$ .— $\text{B}'\text{MeI}$ .

**Methylo-hydroxide**  $\text{B}'\text{MeOH}$  aq [91?], and  $\text{B}'\text{MeOH}$  [138?]. From the methyloiodide and  $\text{Ag}_2\text{O}$  (Schmitt a. Schilling, *A.* 228, 143). Crystals. V. sol. water, alcohol, and chloroform. v. sl. sol. ether or light petroleum. Its solutions are neutral. It is not poisonous. Heated at  $200^\circ$  in the dry state it gives off methylamine while caffeine is also formed.  $\text{HCl}$  or dilute  $\text{H}_2\text{SO}_4$  convert only part of it into the corresponding salt, the rest gives methylamine, formic acid and dimethyldialuric acid, the latter being converted by atmospheric oxygen into amalic acid. When  $\text{HCl}$  is used, caffeine methylochloride is one of the products. With water at  $200^\circ$  it gives sarcosine, methylamine, formic acid, and  $\text{CO}_2$ . Chromic acid forms cholestrophane, methylamine, formic acid and  $\text{CO}_2$ .

**Ethylo-triiodide**  $\text{B}'\text{EtI}_3$ . From caffeine and  $\text{EtI}$  at  $130^\circ$  (Tilden, *C. J.* 18, 99; 19, 145).— $\text{B}'\text{EtI}_3$ ,  $\text{PtCl}_4$ .

**Chloro-caffeine**  $\text{C}_8\text{H}_7\text{ClN}_2\text{O}_2$  [188?]. Formed by passing chlorine into dry caffeine in dry  $\text{CHCl}_3$ . Crystallised from water. V. sl. sol. cold water and ether, v. sol. strong acids but ppd. by water. Reduced to caffeine by zinc-dust and  $\text{HCl}$  (Fischer, *A.* 215, 262; 221, 336).

**Bromo-caffeine** v. p. 561.

**Amido-caffeine**  $\text{C}_8\text{H}_9(\text{NH}_2)\text{N}_2\text{O}_2$  [above  $360^\circ$ ]. From bromo-caffeine (2 pts.) and alcoholic  $\text{NH}_3$  (20 pts.) by heating for 7 hours at  $130^\circ$  (Fischer, *A.* 215, 265). Slender needles; may be distilled. V. sl. sol. water and alcohol; sol. conc.  $\text{HOAc}$ ; sol. conc.  $\text{HCl}$  aq, but reppd. by water, being apparently less basic than caffeine.

**Oxy-caffeine**  $\text{C}_8\text{H}_9(\text{OH})\text{N}_2\text{O}_2$  [c.  $345^\circ$ ]. From ethoxy-caffeine by heating with dilute  $\text{HCl}$  (Fischer, *A.* 215, 268). Mass of white needles (from water). V. sl. sol. alcohol, ether, or cold water. Sol. conc.  $\text{HCl}$  but reppd. by water. Oxy-caffeine is an acid.— $\text{NaA}'$  3aq. Needles.— $\text{BaA}'$  3aq. **Reductions.**—1. The silver salt with  $\text{EtI}$  at  $100^\circ$  gives ethoxy-caffeine.—2.  $\text{POCl}_3$  in  $\text{POCl}_3$  gives chloro-caffeine.—3.  $\text{Cl}$  at a high temperature gives di-methyl-alloxan.—4.  $\text{Cl}$  gas at  $0^\circ$  in a solution of oxy-caffeine in  $\text{HCl}$  gives apo- and hypo-caffeine.—5. Dry bromine forms an addition compound  $\text{C}_8\text{H}_9(\text{OH})\text{N}_2\text{O}_2\text{Br}_2$  (?) as a red mass, decomposed by water or alcohol, the latter giving diethoxy-oxy-caffeine dihydride.

**Ethoxy-caffeine**  $\text{C}_8\text{H}_9(\text{OEt})\text{N}_2\text{O}_2$  [140?]. From bromo-caffeine and alcoholic  $\text{KOH}$  (Fis-

present the formation by oxidation of dimethyl-alloxan and methyl urea. According to Fischer's formula the derivatives of caffeine would be represented as follows: Oxy-caffeine would be

caffeine dihydride would be

caffeine would be

Caffuric acid would be

Hydro-caffuric acid might be written:

Methyl-hydantoin carboxylic acid would be

Hypo-caffeine may be

would be its carboxylic acid. Caffolin may then be

phane  $\text{CO} \begin{cases} \text{CO}-\text{NMe} \\ \text{NMe}-\text{CO} \end{cases}$  from it is in that case

somewhat anomalous.

Strecker's caffeidine (from caffeine by alkalis)

boiling alkalis gives  $\text{CO}_2$ ,  $\text{NH}_3$ ,  $2\text{NMeH}$ , formic acid and sarcosine.

formation of hypo-ethyl-theobromine.

Somewhat similar formulae are arrived at if we start from the formula of Medicus. Inasmuch as caffeine methylo-hydroxide differs from caffeine in giving no  $\text{NH}_3$ , but only  $\text{NMeH}$ , in its decompositions, we must assume that it has the formula

Its decomposition-product, di-methyl-dialuric acid, should, according to Maly a. Hinterberger (*M.* 3, 85), be represented by the formula

which agrees better with the formula of Medicus. On the other hand, the frequent occurrence of methyl-urea as well as *s*-*N*-methyl urea among the decomposition-products of caffeine and its derivatives accords best with Fischer's formula (Schmidt a. Schilling, *A.* 228, 174).

**CAFFEOL**  $\text{C}_8\text{H}_{10}\text{O}_2$ . (196°). Given off (to the extent of .05 p.c.) on roasting coffee together with caffeine (.18 p.c.), palmitic acid, acetic acid,  $\text{CO}_2$ , and traces pyrrol, methylamine, and hydroquinone. It is extracted by ether from the liquid distillate (Bernheimer, *M.* 1, 459). Liquid, smelling like coffee, sl. sol. hot water, v. c. sol. alcohol and ether; v. sl. sol. conc.  $\text{KOH}$  aq.  $\text{FeCl}_3$  colours its alcoholic solution red. Potash-fusion gives salicylic acid. It is perhaps a methyl derivative of *o*-oxy-benzyl alcohol.

**CAFFETANNIC ACID**  $\text{C}_{15}\text{H}_{18}\text{O}_8$ . Occurs in coffee berries to the amount of 3 to 5 p.c. as Ca and Mg salt, and perhaps also as a double salt of K and caffeine (Pfaff, (1830) *Scher.* 61, 487; Rochleder, *A.* 59, 300; 63, 193; 66, 35; 82, 196; Liebig, *A.* 71, 57; Payen, *A. Ch.* [3] 26, 108). Prepared by mixing an alcoholic infusion of coffee with water; filtering from ppd. fatty matter; boiling the filtrate, and ppk. as lead salt by  $\text{Pb}(\text{OAc})_2$ . Colourless mammellated crystalline groups, v. sol. water, m. sol. alcohol; has an astringent taste; strongly reddens litmus.  $\text{FeCl}_3$  colours its solutions green. It does not ppt. ferrous salts, tartar-emetic, or gelatin, but it ppts. quinine and cinchonine. It reduces  $\text{AgNO}_3$  aq. forming a mirror. Its salts turn green in air. Potash-fusion gives protocatechuic acid. Boiling conc.  $\text{KOH}$  aq. splits it up into caffeic acid and a sugar (Hlasiwetz, *A.* 142, 220).

**Salts**.— $\text{BaA}'_2$  (at 100°): amorphous, v. sol. water; addition of baryta forms a yellow pp. —  $\text{PbC}_{15}\text{H}_{18}\text{O}_8$  —  $\text{Pb}_2(\text{C}_{15}\text{H}_{18}\text{O}_8)_2$  —  $\text{Pb}_2\text{C}_{15}\text{H}_{18}\text{O}_8$  (at 100°).

**Viridic acid**. An acid formed by the atmospheric oxidation of an ammoniacal solution of caffeitannic acid. According to Rochleder the green colour of coffee berries is due to calcium viridate. It is ppd. by  $\text{Pb}(\text{OAc})_2$ . Amorphous brown mass, v. sol. water. Conc.  $\text{H}_2\text{SO}_4$  forms a crimson solution whence water gives a flocculent blue pp. The aqueous solutions are turned green by alkalis, and give a bluish-green pp. with baryta-water (cf. Vlaanderen a. Mulder, *J.* 1858, 261).

**CAFFOLIN** v. CAFFEINE.

**CAFFURIC ACID** v. CAFFEINE.

**CAIL-CEDRIN**. A bitter, neutral, resinous substance present to a minute extent in the bark of the *Cail-cedra* (Caventou, *J. Ph.* [8] 16, 855; 83, 123).

**CALCININ**  $C_{10}H_{16}O_8$ . *Calcic acid*. S. 14.

Found in *Calceola* root (from *Chiococca anguifuga* and *racemosa*) (François, Pelletier, & Caventou, *J. Ph.* 16, 465; Liebig, *A. Ch.* [2] 47, 185; Rochleder & Hlasiwetz, *A.* 76, 335; Rochleder, *J. pr.* 85, 275). The root is exhausted with alcohol and the calcinin p<sub>pd</sub>. either by milk of lime or  $Pb(OAc)_2$ . Crystalline flakes, tasteless at first, afterwards very bitter; v. sl. sol. water and ether, v. sol. alcohol; reddens litmus. Boiling alcoholic HCl splits it up into a sugar ( $C_{12}H_{22}O_{11}$ ) and crystalline calcioetin  $C_{22}H_{34}O_{12}$ . Calcioetin is resolved by potash-fusion into butyric acid and calcioigenin  $C_{11}H_{18}O_2$  which is possibly related to asceigenin. Calcioetin in dilute alcoholic solution is converted by sodium-amalgam into crystalline  $C_{20}H_{32}O_{10}$ , whence fuming HCl forms gelatinous  $C_{18}H_{26}O_8$ .

**CAJEPUT, OIL OF.** A light green oil prepared in India by distilling the leaves of *Melaleuca leucodendron* with water. Its chief constituent is cineol  $C_{10}H_{18}O$  (q. v.), which is also called cajeputol.  $P_2O_5$  converts it into terpenes (q. v.) which when so obtained may be called cajeputenes (Schmidt, *C. J.* 14, 63; Wright & Lambert, *C. J.* 27, 619; Histed, *Ph.* [3] 2, 804; Blanchet, *A.* 7, 161; Gladstone, *C. J.* 49, 621).

**CALAMUS ROOT.** According to Genthner (*A.* 240, 92) the acorin prepared by Thoms (p. 60) from *Acorus calamus* is not a definite substance, but is separated by alkalis into a neutral amorphous brown mass ( $C_{10}H_{16}NO_2$ ?) and an acid ( $C_{11}H_{18}O_2$ ?). Calamus root after extraction with water still contains a combined acid ( $C_{11}H_{18}O_2$ ?) which may be extracted by adding HCl and shaking with ether. When the root is distilled with steam, in ethyl alcohol and a mixture of terpenes (q. v.) and a compound  $C_{10}H_{16}O$  (?) is obtained (G.; Sekredermann, *A.* 41, 374; Kurbetow, *B.* 6, 1210; Gladstone, *C. J.* 17, 1).

**CALCIUM.** Ca. At. w. 39.91. Mol. w. unknown. Melts at red heat. S.G. 1.57 (Matthiessen, *A.* 93, 27). S.H. (0°–100°) 1.686 (Bunsen, *P.* 141, 1). S.V.S. abt. 25. E.C. (Hg at 0° = 1) 12.5 (Matthiessen, *P. M.* [4] 12, 199; 13, 81). Chief lines in emission-spectrum, 6121.2, 5587.6, 4226.3, 3968, 3932.8.

**Occurrence.**—Never free. Very widely distributed, and often in large quantities, as silicate, phosphate, sulphate, carbonate, fluoride, &c. Most natural waters contain Ca salts; phosphate and carbonate of Ca are found in plants and animals. Ca salts occur in the sun, fixed stars, and meteorites. Calcium carbonate and burnt lime have been known from very ancient times. In 1722 Fr. Hoffmann showed that lime is a distinct earth; Black (1755) was the first to make a quantitative examination of limestone and burnt lime. In 1808 Davy obtained calcium (impure) by the electrolysis of lime.

**Formation.**—1. Dry  $CaCl_2$  is heated with Na in an iron crucible with an air-tight cover (Liébe-Bodart & Jobin, *A. Ch.* [3] 64, 363; Dumas, *C. R.* 47, 575; Sonstadt, *C. N.* 9, 140).—2. Dry fused  $CaCl_2$  (800 parts), Na (100 parts), and pure distilled granulated Zn (400 parts), are heated in a crucible with loosely fitting lid, as high a temperature being maintained as is

possible without volatilisation of much Zn; an alloy of Ca and Zn is thus produced ( $Zn_2Ca$  according to v. Rath, *P.* 136, 434). This alloy is heated in a crucible of gas coke until the Zn is all distilled off (Caron, *C. R.* 48, 450; 50, 547).—3. A boiling conc. solution of  $CaCl_2$  is electrolysed, using an amalgamated Pt wire as negative electrode (Bunsen, *A.* 92, 218).

**Preparation.**—A mixture of dry  $CaCl_2$  and  $SrCl_2$  in the ratio  $2CaCl_2:SrCl_2$ , mixed with a little  $NH_4Cl$ , is melted in an open crucible; the current from 3 or 4 Bunsen cells is passed through the molten mass, the positive electrode being a stick of carbon, and the negative an iron wire as thick as a knitting needle, drawn out to a fine point. The point of the iron wire is kept just under the surface of the molten mass for a minute or so at a time; the Ca separates in small lumps (Matthiessen, *A.* 93, 277; 94, 108). Frey obtained lumps of Ca weighing from 2½ to 4 grams (*A.* 183, 367); he passed the negative electrode through the stem of a tobacco pipe with the bowl dipping under the molten mass in the crucible; it was then passed into the pipe; when the pipe and bowl were filled with this gas, the H was stopped, and the current was started; the Ca rose into the bowl of the pipe, and being in contact with H remained quite unoxidised.

**Properties.**—Lustrous, clear yellowish-white, very ductile, but brittle when hammered out, malleable; about as hard as calspar. Frey (*A.* 183, 367) says it is brittle and cannot be hammered out or drawn into wire. Melts at full red heat, and then burns with yellow flame and production of much heat and light;  $[Ca, O] = 130,930$  (*Th.* 3, 251). Does not oxidise in dry air; but in ordinary air is quickly covered with  $CaO$ . Not volatilised at temperature of inflammation (Caron, *C. R.* 48, 410). Decomposes cold  $H_2O$  rapidly;

$[Ca, Aq] = [Ca, O^2, H^2, Aq] - 2[H^2, O] = 80,900$  (*Th.* 3, 251). As no compound of Ca has been gasified, the value to be given to the atomic weight of the metal is decided partly by the S.H. and partly by purely chemical considerations. The mass of Ca that combines with 15.96 (i.e. with 1 atom) O is 39.91, hence the simplest formula for the oxide is  $CaO$  ( $Ca = 39.91$ ); the same mass of Ca combines with  $2 \times 35.37$  Cl,  $2 \times 79.75$  Br, &c.; the simplest formulae for the chloride and bromide are therefore  $CaCl_2$  and  $CaBr_2$ , respectively ( $Ca = 39.91$ ). These formulae are in keeping with the reactions of the compounds, hence they are adopted. The chief compounds of Ca by analyses of which the value  $Ca = 39.91$  has been found are: (1)  $CaCl_2$  (Berzelius, *G. A.* 57, 451; Dumas, *A. Ch.* [3] 55, 190); (2)  $CaCO_3$  converted into  $CaO$  (Dumas, *C. R.* 14, 537; Erdmann & Marchand, *J. pr.* 26, 472). Ca is a strongly positive metal, forming well-marked and stable salts by replacing the H of acids. Salts of Ca derived from almost every acid are known; several of these form double salts; very few basic salts are known.  $CaO.H_2O$  is an alkaline hydroxide;  $CaO$  combines with  $H_2O$  with production of much heat;  $CaO.H_2O$  is dehydrated to  $CaO$  at a high temperature.  $[CaO, H^2O] = 15,540$  (*Th.* 3, 251). The heat of neutralisation of  $CaO.H_2Aq$  is the same as that of  $KOHAq$ .

## CALCIUM

NaOH.Aq. and BaO.H.Aq. viz. 31,750 for H<sub>2</sub>SO<sub>4</sub>.Aq and 27,640 for HCl.Aq. Ca combines with the halogens with production of heat; [Ca.X] = 169,820 when X = Cl; 140,850 when X = Br; 107,250 when X = I (Th. 3, 251).

**Reactions and Combinations.**—1. With water forms CaO.Aq and H.—2. With acids forms salts, usually evolving H; conc. HNO<sub>3</sub>.Aq only acts at high temperatures.—3. Combines directly, when heated, with many non-metals; especially Cl, Br, I, O, S, P (v. CALCIUM CHLORIDE, &c.).—4. Forms alloys with several metals, by heating the metals together. Alloys with Al, Sb, Pb, Hg, Na, and Zn have been described (Caron, C. R. 48, 440; 50, 547; Wöhler, A. 138, 253). Calcium is usually estimated either as carbonate or sulphate, or volumetrically, by K<sub>2</sub>Mn<sub>2</sub>O<sub>8</sub>.Aq, after pptn. as CaC<sub>2</sub>O<sub>4</sub> and decomposition of this salt by H<sub>2</sub>SO<sub>4</sub>.Aq.

**Calcium, Alloys of, v. CALCIUM; Combinations, No. 4.**

**Calcium, Arsenates of.** CaHAsO<sub>4</sub> and Ca<sub>3</sub>(AsO<sub>4</sub>)<sub>2</sub>: v. ARSENATES, under ARSENIC, ACIDS OF.

**Calcium, Arsenites of.** Ca<sub>2</sub>(AsO<sub>3</sub>)<sub>2</sub>; Ca(AsO<sub>3</sub>)<sub>2</sub>; and Ca<sub>3</sub>As<sub>2</sub>O<sub>6</sub>: v. ARSENITES, under ARSENIC, ACIDS OF.

**Calcium, Bromide of.** CaBr<sub>2</sub>. Mol. w. unknown, as compound has not been gasified. [676°-680°] (Carnelley, C. J. 29, 497; 33, 279). S.G. 3.32 (Kopp, A. 93, 129). S. (0°) 125; (20°) 141; (40°) 212; (60°) 277; (105°) 312 (Kremers, P. 103, 65). H.F. [Ca.Br] = 140,850; [Ca.Br<sub>2</sub>.Aq] = 165,360 (Thomsen).

**Formation.**—CaBr<sub>2</sub> is formed by dissolving CaO or CaCO<sub>3</sub> in HBr.Aq, evaporating, and crystallising; or by decomposing Fe<sub>2</sub>Br<sub>9</sub>.Aq by CaO.Aq.

**Preparation.**—1. 12½ parts Br and 1 part amorphous P are allowed to react in presence of H<sub>2</sub>O; the solution is neutralised by CaCO<sub>3</sub> or CaOH<sub>2</sub>, filtered from Ca<sub>2</sub>P<sub>2</sub>O<sub>7</sub>, evaporated, and crystallised (Klein, A. 128, 237).—2. 20 parts S are dissolved in 240 parts Br, and the liquid is poured into thin milk of lime, containing 140 parts CaO; CaSO<sub>4</sub> is pptd. by alcohol, the solution is filtered off, evaporated, and crystallised (Faust, Ar. Ph. [2] 131, 216).

**Properties.**—White, lustrous, deliquescent, needles; very soluble in H<sub>2</sub>O and alcohol. Absorbs NH<sub>3</sub>, forming CaBr<sub>2</sub>.6NH<sub>3</sub> (Rammelsberg, P. 55, 239). CaBr<sub>2</sub>.Aq boiled with CaO<sub>2</sub>H<sub>2</sub>, and filtered, on cooling yields crystals of CaBr<sub>2</sub>.3CaO.15H<sub>2</sub>O.

**Combinations.**—With water to form CaBr<sub>2</sub>.6H<sub>2</sub>O. [CaBr<sub>2</sub>.6H<sub>2</sub>O] = 25,600; [CaBr<sub>2</sub>.6H<sub>2</sub>O.Aq] = -1690 (Th. 3, 251).

**Calcium Bromide, hydrated, v. CALCIUM, BROMIDE OF, Combinations.**

**Calcium, Chloride of.** CaCl<sub>2</sub>. Mol. w. unknown, as compound has not been gasified. [719°-723°] (Carnelley, C. J. 29, 497). S.G. 2.205 (Schiff, A. 108, 23). S.H. (23°-99°) 1642 (Regnault, A. Ch. [3] 1, 129). S. (0°) 49.6; (10°) 60; (20°) 74; (30°) 93; (35°) 104; (40°) 110; (50°) 120; (60°) 123; (70°) 136; (80°) 142; (90°) 147; (95°) 151; (99°) 154 (Mulder, J. 1866, 66). H.F. [Ca.Cl] = 169,820; [Ca.Cl<sub>2</sub>.Aq] = 187,230 (Thomsen).

**Formation.**—In making NH<sub>3</sub> by the action

of CaO.H<sub>2</sub> on NH<sub>4</sub>Cl.Aq; also as a by-product in many chemical manufactures.

**Preparation.**—1. Pure CaCO<sub>3</sub> is dissolved in pure HCl.Aq; the solution is evaporated to dryness and heated to about 200°.—2. Ordinary marble or chalk is dissolved in HCl.Aq, Cl is led into the acid liquid until all Fe and Mn salts are completely oxidised. Milk of lime is added to alkaline reaction, the whole is digested, the liquid is filtered from lime and pptd., oxides of Mg, Fe, and Mn, neutralised by HCl.Aq, and evaporated as in 1.

**Properties and Reactions.**—A white, porous, very deliquescent, solid; after melting and cooling it is distinctly crystalline. Absorbs moisture rapidly; hence is much used for drying gases, &c.; if the CaCl<sub>2</sub> to be used must be free from CaO, e.g. for drying CO<sub>2</sub>, it should be placed for some time in a stream of CO<sub>2</sub>, and then of dry air at the ordinary temperature. CaCl<sub>2</sub> is very soluble in water and alcohol, much less soluble in HCl.Aq. It is partly decomposed by heating in air (v. Weber, B. 15, 2316), more completely by heating in O, with production of CaO. Heated with KClO<sub>4</sub> or KClO<sub>3</sub>, part of it is changed to CaO (Schulze, J. pr. [2] 21, 407). CaCl<sub>2</sub>.Aq is used as a bath for maintaining temperatures above 100°; 50 parts CaCl<sub>2</sub> in 100 parts H<sub>2</sub>O forms a solution boiling at 112°; 100 CaCl<sub>2</sub> in 100 water, B.P. 128°; 200 CaCl<sub>2</sub> in 100 H<sub>2</sub>O, B.P. 158°; and 325 CaCl<sub>2</sub> in 100 H<sub>2</sub>O, B.P. 180° (Magnus, P. 112, 408; Wüllner, P. 110, 564; Legrand, A. 17, 34).

**Combinations.**—1. With water to form hexagonal crystals of CaCl<sub>2</sub>.6H<sub>2</sub>O [CaCl<sub>2</sub>.6H<sub>2</sub>O] = 21,750 (Th. 3, 251); best prepared by evaporating a solution of CaCO<sub>3</sub>, or CaO, in HCl.Aq and crystallising. CaCl<sub>2</sub>.6H<sub>2</sub>O melts at 28° (Tilden, C. J. 45, 268); heated to 230°, or placed *in vacuo*, the hydrate CaCl<sub>2</sub>.2H<sub>2</sub>O remains. This hydrate is also produced, according to Ditte (C. R. 92, 212), by saturating HCl.Aq with CaCl<sub>2</sub> at 12° and cooling. Hamerl (Sitz. W. (2nd part) 72, 667) says that CaCl<sub>2</sub>.4H<sub>2</sub>O is formed by repeatedly melting and cooling CaCl<sub>2</sub>.6H<sub>2</sub>O. According to Dibbitts (Ar. N. 13, 478) CaCl<sub>2</sub>.6H<sub>2</sub>O loses 4H<sub>2</sub>O in a current of dry air, and 6H<sub>2</sub>O in dry air at 80°. S.G. 1.2° of CaCl<sub>2</sub>.6H<sub>2</sub>O, 1.612 (Kopp, A. 93, 129). S.H. of CaCl<sub>2</sub>.6H<sub>2</sub>O (-20° to 2°) 345; (4°-28°) 647; melted (34°-59°) 5601, (34°-99°) 552, (100°-127°) 519 (Person, C. R. 23, 162). C.E. (cubical) for solid CaCl<sub>2</sub>.6H<sub>2</sub>O; V<sub>1</sub>=V<sub>0</sub> (1+000 645 12-000 053 774+000 001 906 2°) for interval 11°-26° (Kopp, A. 93, 129). H.F. [Ca.Cl<sub>2</sub>.6H<sub>2</sub>O] = 191,980; CaCl<sub>2</sub>.6H<sub>2</sub>O dissolves in water with disappearance of much heat [CaCl<sub>2</sub>.6H<sub>2</sub>O.Aq] = -4,340 (Thomsen). This salt mixed with snow produces great lowering of temperature; for use as a freezing mixture the salt is best prepared by boiling a conc. solution until temperature rises above 129°, then allowing to cool, shaking well as the solid forms. CaCl<sub>2</sub>.6H<sub>2</sub>O is thus obtained as a fine dry powder; 4 parts are mixed with 3 parts dry snow. Hamerl (Sitz. W. (2nd part) 78, 59) observed -51.9° by mixing this salt with dry snow, both cooled under 0°, in the ratio CaCl<sub>2</sub>.6H<sub>2</sub>O: 8.45 H<sub>2</sub>O (as snow). CaCl<sub>2</sub>.6H<sub>2</sub>O: S (0°) 72.8; (13.8°) 80.9; (24.5°) 89.5; (29.5°) 100 (Hamerl, Sitz. W. (2nd part) 72, 287).—2. With

ammonia forms  $\text{CaCl}_2 \cdot 8\text{NH}_3$ ; dissociated by heat into  $\text{CaCl}_2$  and  $8\text{NH}_3$ ;  $\text{NH}_3$  also removed by dissolving in  $\text{H}_2\text{O}$  and passing in a current of air (Weber, *B.* 15, 2318). Isambert (*O. R.* 66, 1259) describes  $\text{CaCl}_2 \cdot 4\text{NH}_3$  and  $\text{CaCl}_2 \cdot 2\text{NH}_3$ ; he gives these thermal values  $\frac{1}{2}[\text{CaCl}_2 \cdot 2\text{NH}_3] = 14,000$ ;  $\frac{1}{2}[\text{CaCl}_2 \cdot 4\text{NH}_3] = 12,200$ ;  $\frac{1}{2}[\text{CaCl}_2 \cdot 8\text{NH}_3] = 11,000$  (*O. R.* 86, 968).—8. With alcohol to form  $\text{CaCl}_2 \cdot 2\text{C}_2\text{H}_5\text{O}$ ; decomposed by  $\text{H}_2\text{O}$  (Chodnew, *A.* 71, 241; Johnson, *J. pr.* 62, 264). Forms combinations also with acetone (Hlasiwetz, *A.* 76, 294).—4. With lime to form  $\text{CaCl}_2 \cdot 3\text{CaO} \cdot 15\text{H}_2\text{O}$ ; prepared by boiling  $\text{CaCl}_2$  aq with  $\text{CaO} \cdot \text{H}_2\text{O}$ , filtering while hot, and allowing to cool; decomposed by  $\text{H}_2\text{O}$  or  $\text{C}_2\text{H}_5\text{O}$  (Beesley, *Ph.* 9, 56; Rose, *S.* 29, 155; Bolley, *D. P. J.* 153, 202; Grimshaw, *C. N.* 30, 280).—5. With platinous chloride to form  $\text{CaCl}_2 \cdot \text{PtCl}_2 \cdot 8\text{H}_2\text{O}$ ;  $\text{M.P.} = 100^\circ$  (Nilson, *J. pr.* [2] 15, 260).

**Calcium chloride, hydrated, v. CALCIUM, CHLORIDE OF; Combinations, No. 1.**

**Calcium, Cyanide of.**  $\text{Ca}(\text{CN})_2$ . Said to be obtained by heating  $\text{Ca}$  ferrocyanide and dissolving out with water (Schulz, *J. pr.* 68, 257). v. CYANIDES.

**Calcium, Fluoride of.**  $\text{CaF}_2$ . Mol. w. unknown, as compound has not been gasified. [abt. 902°] (Carnelley, *C. J.* 33, 280).  $\text{S.G.}_{\frac{\text{abt. } 150^\circ}{4^\circ}} 3.15-3.18$  (Schröder, *Dichtigkeitsmessungen* (Heidelberg, 1873); Kengott, *Sitz. W.* 10, 295).  $\text{S.H.}$  (21°–50°) 209 (Kopp, *T.* 155, 71); (15°–99°) 2154 (Regnault, *A. Ch.* [3] 1, 129). Index of refraction at 21° for line B = 1.432; line D = 1.4339; line F = 1.43709; line G = 1.43982; line H = 1.44204 (Stefan, *Sitz. W.* 63 (2nd part), 239).  $\text{S.}$  (15°) 0004 (Wilson, *J.* 1850, 278).  $[\text{CaH}_2\text{O} \cdot 2\text{HF}] = 66,600$  (Guntz, *C. R.* 97, 1483, 1558; 98, 816).

**Occurrence.**—As *Fluorspar*, in octahedra, cubes, and other forms of the monometric system, fairly widely distributed in many rocks; in small quantities in many mineral waters, plantash, bones (Lassaigne, *S.* 52, 141), enamel of teeth, &c.

**Preparation.**—1. As a gelatinous mass, by decomposing an aqueous solution of a  $\text{Ca}$  salt by that of a fluoride.—2. As a granular powder by digesting freshly ppd.  $\text{CaCO}_3$  with  $\text{HFAq}$ .—3. In small octahedra by digesting the gelatinous pp. obtained in 1 with dilute  $\text{HClAq}$  for 10 hours at 240° (Sénarmont, *A. Ch.* [3] 32, 123; Scheerer a. Drechsel, *J. pr.* [2] 7, 63).

**Properties and Reactions.**—Transparent, colourless crystals, melting without decomposition at about 900°. Forms easily fusible mass with  $\text{BaSO}_4$ ,  $\text{SrSO}_4$ , and many other insoluble compounds; hence much used as a flux. Soluble in aqueous solutions of  $\text{NH}_3$  salts (Rose, *P.* 79, 112). Not decomposed by fusion with  $\text{KOH}$  or  $\text{NaOH}$ , but partially by fusion with excess of alkali carbonates. Decomposed, to  $\text{CaO}$  and  $\text{HF}$ , by heating to redness in steam; also decomposed by hot  $\text{H}_2\text{SO}_4$  aq, but only very partially by boiling  $\text{HClAq}$  or  $\text{HNO}_3$  aq. Said to be partly decomposed by  $\text{Al}$ ,  $3\text{SO}_4$  aq (Friedel, *Bl.* [2] 21, 241).

**Combinations.**—With hydrofluoric acid and water to form  $\text{CaF}_2 \cdot 2\text{HF} \cdot 6\text{H}_2\text{O}$ ; produced in small crystals by evaporating a solution of  $\text{CaO}$  in large excess of  $\text{HFAq}$ ; decomposed to  $\text{CaF}_2$

and  $\text{HFAq}$  by hot water (Fremy, *A. Ch.* [3] 47 85).

**Calcium, Hydrate of,  $\text{CaO} \cdot \text{H}_2\text{O}$ , v. CALCIUM HYDROXIDE OF.**

**Calcium, Hydrosulphide of, v. CALCIUM SULPHIDE.**

**Calcium, Hydroxide of,  $\text{CaO} \cdot \text{H}_2\text{O}$  (Slaked lime.)** Mol. w. unknown; compound is decomposed by heat.  $\text{S.G.}$  2.078 (Filhor, *A. Ch.* [3] 21, 415).  $\text{S.G.}_{\frac{\infty}{0^\circ}}$  (crystalline) 2.236 (Lamy, *A. Ch.* [5] 14, 145).  $\text{S.}$  (15°) 13; (54°) 103; (100°) 08 (Dalton, *New System*, 2, 331);  $\text{S.}$  (18°) 13; (100°) 07 (Bineau, *C. R.* 41, 509, v. also Lamy, *C. R.* 36, 333).  $\text{H.F.}$   $[\text{CaO} \cdot \text{H}_2\text{O}] = 146,470$ ;  $[\text{CaO} \cdot \text{H}_2\text{O}] = 13,510$  (*T.* 3, 251).

**Preparation.**—1. By adding to 1 part  $\text{H}_2\text{O}$  3.1 parts  $\text{CaO}$ .—2. By allowing  $\text{Ca}$  to oxidise in moist air. 3. By adding  $\text{KOH}$  aq, or  $\text{NaOH}$  aq, to a conc. aqueous solution of a  $\text{Ca}$  salt, collecting pp., washing well, and drying at 100°. Gay-Lussac (*A. Ch.* 1, 331) obtained  $\text{CaO} \cdot \text{H}_2\text{O}$  in small six-sided plates by evaporating an aqueous solution over  $\text{H}_2\text{SO}_4$  in *vacuo*.

**Properties and Reactions.**—A white, compact mass; slightly soluble in cold, less soluble in hot, water  $[\text{CaO} \cdot \text{H}_2\text{O}] = 2,290$  (*Th.* 3, 251). Strongly alkaline reaction.  $\text{CaO} \cdot \text{H}_2\text{O}$  neutralises acids with production of same quantity of heat as when  $2\text{NaOH}$  aq, or  $2\text{KOH}$  aq is used, viz. about 31,000 for  $\text{H}_2\text{SO}_4$  aq, and about 27,900 for  $2\text{HCl}$  aq (Thomson); also pps. many heavy metals as oxides or hydroxides, and saponifies fats. Moist  $\text{CaH}_2\text{O}_2$  absorbs  $\text{CO}_2$ , forming  $\text{CaCO}_3$  and  $\text{H}_2\text{O}$ .  $\text{CaLi}_2\text{O}_2$  forms insoluble salts when neutralised by  $\text{H}_2\text{SiO}_4$  aq,  $\text{H}_2\text{BO}_3$  aq,  $\text{H}_3\text{PO}_4$  aq, &c.; pps. are also formed by adding animal char, sand, &c.  $\text{CaH}_2\text{O}_2$  is soluble in solutions of cane sugar; on adding alcohol pps. are obtained, said to have the compositions

(Pelouze, *J.* 1861, 572; Bowin a. Loiseau, *A. Ch.* [4] 6, 203; Péligot, *A. Ch.* [3] 54, 383; Déon, *Bl.* [2] 17, 155; Berthelot, *A. Ch.* [3] 46, 173).  $\text{CaH}_2\text{O}_2$  is much more soluble in glycerin than in water. At a bright red heat  $\text{CaH}_2\text{O}_2$  is decomposed to  $\text{CaO} + \text{H}_2\text{O}$ . For reaction between  $\text{Cl}$  and  $\text{CaH}_2\text{O}_2$  v. *Blanching Powder* under **HYPOCHLORITES**, under **CHLORINE**, **OXYACIDS OF**.

**Calcium, Iodide of.**  $\text{CaI}_2$ . Mol. w. unknown, as compound has not been gasified. [331°] (Carnelley, *C. J.* 33, 279).  $\text{S.}$  (0°) 192; (20°) 204; (40°) 2.8; (43°) 286; (92°) 435 (Kremers, *P.* 103, 65).  $\text{H. F.}$   $[\text{Ca}, \text{I}] = 107,250$ ;  $[\text{Ca}, \text{I}, \text{Aq}] = 134,940$  (*Ph.* 3, 251).

**Formation.**—By the action of  $\text{HIAq}$  on  $\text{CaO} \cdot \text{H}_2\text{O}$ ; or of  $\text{I}$  on  $\text{CaS}$  suspended in water (Lies-Bodart a. Robin, *A. Ch.* [3] 54, 363).

**Preparation.**—To 1 part amorphous  $\text{P}$  and 40 parts  $\text{H}_2\text{O}$ , 20 parts  $\text{I}$  are slowly added; the whole is digested at 100°; the colourless liquid is neutralised by milk of lime, and evaporated in an atmosphere free from  $\text{CO}_2$  (Liebig, *A.* 121, 222; Wagner, *C. R.* 1862, 113).

**Properties and Reactions.**—White, deliquescent mass; very soluble in water and alcohol; undecomposed when melted out of contact with air; melted in air gives  $\text{CaO}$  and  $\text{I}$ . Conc.  $\text{CaI}_2$  aq dissolves  $\text{I}$ ; on evaporation in *vacuo* crystals of a periodide are said to be obtained.

Absorbs  $6\text{NH}_3$  (Isambert, *C. A.* 66, 1259). Forms an easily decomposed double compound with AgI:  $\text{CaI}_2 \cdot 2\text{AgI} \cdot 6\text{H}_2\text{O}$  (Simpson, *Pr.* 27, 120).

Calcium hydroxyhydrosulphide *v. post* (under CALCIUM SULPHYDRATE).

Calcium, Oxides of. Two oxides are known;  $\text{CaO}$  a strongly basic compound, and  $\text{CaO}_2$  which acts as a peroxide.  $\text{CaO}_2$  cannot be formed by the action of  $\text{O}$  on  $\text{CaO}$  (*comp.*  $\text{BaO}_2$ ).

I. CALCIUM MONOXIDE.  $\text{CaO}$  (*Lime, burnt lime*). Mol. w. unknown, as compound has not been gasified. S.G. 3.15 (Schröder, *P. Jubelbl.* 452); S.G. (crystalline, by heating  $\text{Ca}_2\text{NO}_3$ ) 3.251 (Brügelmann, *W.* 2, 466; 4, 277). S. variable according to state of aggregation of the  $\text{CaO}$  &c. Lamy (*A. Ch.* 15) 14, 135 gives the following numbers representing grams of  $\text{CaO}$  in 1000 grams of solution;  $\text{CaO}$  being made (1) by heating  $\text{Ca}_2\text{NO}_3$ , (2) by heating  $\text{CaCO}_3$ , (3) by heating  $\text{CaO}_2\text{H}_2$ :—

Temp.	(1)	(2)	(3)
0°	1.362	1.381	1.430
10	1.311	1.342	1.384
15	1.277	1.299	1.348
30	1.142	1.162	1.195
45	0.996	1.005	1.033
60	0.844	0.868	0.885
100	0.562	0.576	0.584

H. F.  $[\text{Ca}, \text{O}] = 130,930$ ;  $[\text{Ca}, \text{O}, \text{Ag}] = 149,260$  (*Th.* 3, 251).

*Preparation.*—Pure marble, or Iceland spar, is strongly heated in a crucible with a hot fire in the bottom to allow escape of  $\text{CO}_2$ ; or a piece of charcoal is placed in the crucible beneath the marble,  $\text{CO}$  is thus formed and sweeps out the  $\text{CO}_2$  with it.  $\text{CaCO}_3$  is not completely decomposed when heated in an atmosphere of  $\text{CO}_2$ ;

*v.* CALCIUM CARBONATE, under CARBONATES. Sestini (*Fr.* 4, 51) strongly heats powdered marble with sugar, washes with  $\text{H}_2\text{O}$ , dissolves in  $\text{HNO}_3\text{Aq}$ , pps.  $\text{CaCO}_3$  by  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ , and strongly heats the dried pp. By strongly heating  $\text{Ca}_2\text{NO}_3$  in quantities of about 15–20 grams at a time, in a porcelain flask, Brügelmann (*W.* 2, 466; 4, 277) obtained cubical crystals of  $\text{CaO}$ ; semitransparent, harder than the amorphous form, and less easily acted on by  $\text{H}_2\text{O}$  and  $\text{CO}_2$ .

*Properties and Reactions.*—White, amorphous (or crystalline *v. supra*), powder: does not fuse at full white heat. Strongly basic; reacts with most acids to form salts.  $\text{CaO}$  is decomposed by heating to whiteness with  $\text{K}$ ; heated in  $\text{Cl}$ ,  $\text{CaCl}_2$  is formed.  $\text{CaS}$  is produced by heating with  $\text{S}$ , and  $\text{CaS}$  and  $\text{CaCO}_3$  by heating in  $\text{CS}_2$ .  $\text{CaG}$  does not combine with  $\text{O}$  (*v.* Conroy, *C. J.* [2] 11, 809).

*Combinations.*—With carbon dioxide to form  $\text{CaCO}_3$  (but dry  $\text{CaO}$  does not react with  $\text{CO}_2$ ; Scheibler, *B.* 19, 1973); combination begins at about  $400^\circ$  (*v.* Birnbaum a. Mahn, *B.* 12, 1547);  $[\text{CaO}, \text{CO}_2] = 42,520$  (*Th.* 3, 251). Heated with silica or silicates, silicates of  $\text{Ca}$  are formed, which in contact with water set to a hard compact mass (hydraulic mortars). With water,  $\text{CaO}_2\text{H}_2$  is formed with production of much heat  $[\text{CaO}, \text{H}_2\text{O}] = 15,540$  (Thomsen); the lime is said to be slaked.

II. CALCIUM DIOXIDE,  $\text{CaO}_2$  (*Calcium peroxide*). Mol. w. unknown. Prepared by adding pure  $\text{H}_2\text{O}_2\text{Aq}$  to excess of  $\text{CaOAq}$ , or by adding excess of  $\text{CaOAq}$  to  $\text{Na}_2\text{O}_2\text{Aq}$  containing some

$\text{HNO}_3\text{Aq}$ ; collecting pp., washing well with acid water, and heating the  $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$  thus produced in a current of dry air free from  $\text{CO}_2$  to  $100^\circ - 120^\circ$ . Forms a snow-white crystalline powder; does not melt at red heat, but gives off  $\text{O}$  and forms  $\text{CaO}$ . The hydrate  $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$  is slightly soluble in  $\text{H}_2\text{O}$ , in contact with  $\text{H}_2\text{O}$  it slowly decomposes to  $\text{CaO}_2\text{H}_2\text{Aq}$  and  $\text{H}_2$ ; soluble in  $\text{NH}_4\text{ClAq}$ , but not in  $\text{NH}_3\text{Aq}$ ; dissolves easily in dilute acids, even in  $\text{H}_2\text{C}_2\text{H}_3\text{O}_2\text{Aq}$ , without evolution of  $\text{O}$ . It forms prismatic dimetric crystals, isomorphous with  $\text{BaO}_2 \cdot 8\text{H}_2\text{O}$  and  $\text{SrO}_2 \cdot 8\text{H}_2\text{O}$  (Schöne) (Thénard, *A. Ch.* [2] 8, 306; Conroy, *C. J.* [2] 11, 808; Schöne, *B.* 6, 1172).

Calcium oxide, hydrated,  $\text{CaO}_2\text{H}_2$ , *v.* CALCIUM HYDROXIDE OF.

Calcium, Oxybromide of,  $\text{CaBr}_2 \cdot 3\text{CaO} \cdot 15\text{H}_2\text{O}$  *v.* CALCIUM, BROMIDE OF; *Properties.*

Calcium, Oxychloride of,  $\text{CaCl}_2 \cdot 3\text{CaO} \cdot 15\text{H}_2\text{O}$ , *v.* CALCIUM, CHLORIDE OF; *Combinations*, No. 4.

Calcium, Oxysulphides of, *v.* CALCIUM POLY-SULPHIDES; under CALCIUM, SULPHIDES OF.

Calcium, Phosphide of. When  $\text{Ca}$  and  $\text{P}$  are heated under rock oil, and the unacted-on  $\text{P}$  is dissolved out by  $\text{CS}_2$ , a black powder remains which is acted on by  $\text{H}_2\text{O}$  and acids with production of  $\text{PH}_3$ ; this black powder is said by Vigier to be  $\text{Ca}$  phosphide (*Bz.* 1861. 5). By strongly heating  $\text{CaO}$  in  $\text{P}$  vapour, a brown, amorphous mass is obtained; when heated with conc.  $\text{HClAq}$ , non-inflammable  $\text{PH}_3$  is evolved, but with dilute  $\text{HClAq}$  the gas evolved takes fire. Probably in the first case liquid  $\text{PH}_3$  is formed and at once decomposed to gaseous  $\text{PH}_3$  and solid  $\text{P}_2\text{H}_4$ ; in the second case the decomposition of  $\text{PH}_3$  proceeds more slowly, so that some is carried into the air with the  $\text{PH}_3$  and causes the combustion. (Thénard, *A. Ch.* [3] 14, 12). The brown substance got by heating  $\text{CaO}$  in  $\text{P}$  vapour is said to be a mixture of  $\text{CaP}$  and  $\text{Ca}_3\text{P}_2\text{O}_7$  (Thénard, *loc.*): this brown substance is described by Thénard as a very hard solid; unchanged in dry air; deliquescent in moist air; burns when heated in air; acted on by water free from air gives  $\text{CaOAq}$  and  $\text{PH}_3$ .  $\text{PH}_3$  decomposes to  $\text{PH}_4$  and  $\text{P}_2\text{H}_4$ , and the  $\text{P}_2\text{H}_4$  is decomposed by the  $\text{CaOAq}$  to  $\text{Ca}(\text{H}_2\text{PO}_4)_2\text{Aq}$  and  $\text{H}_2$ .

Calcium, Salts of. Compounds obtained by replacing  $\text{H}$  of acids by  $\text{Ca}$ . These salts form one series  $\text{CaX}_2$ , where  $\text{X}_2 = \text{Cl}_2, (\text{NO}_3)_2, \text{SO}_4, \frac{2}{3}\text{PO}_4$ , &c. They are generally formed by the action of  $\text{CaO}$  or  $\text{CaO}_2\text{H}_2$  on the acids in aqueous solution, or by the decomposition of salts of the heavier metals by  $\text{CaO}_2\text{H}_2\text{Aq}$ . As none of the  $\text{Ca}$  salts has been gasified, the formulæ are based partly on similarities between these salts and those of analogous metals which form gasifiable compounds, chiefly  $\text{Zn}$ ,  $\text{Cd}$ , and  $\text{Hg}$ , and partly on the fact that the general formula  $\text{CaX}_2$  is the simplest that can be given, provided the atomic weight of  $\text{Ca}$  is about 40 (this has been established by analyses of  $\text{CaCl}_2$ ,  $\text{CaCO}_3$ , &c. and by determinations of the S.H. of the metal; *v.* CALCIUM). Salts of  $\text{Ca}$  derived from a great many acids are known; they are well marked stable bodies; many form double salts; few basic salts are known. Most of the  $\text{Ca}$  salts are soluble in water; the more insoluble are the arsenite, carbonate, fluoride, oxalate, phosphate, sulphate, and sulphite. With the exception of  $\text{CaF}_2$ , all the salts are more or less

soluble in dilute acids. The Ca salts of non-volatile acids are generally undecomposed by heat. Ca salts derived from a great many acids are known (*v.* BORATES, CARBONATES, PHOSPHATES, SULPHATES, &c., &c.).

**Calcium, Selenide of.**  $\text{CaSe}$ . Mol. w. unknown. White solid, rapidly changing in air, prepared by heating  $\text{CaSeO}_3$  to dull redness in  $\text{H}_2$ ;  $[\text{Ca}, \text{Se}] = 78,000$  (Fabre, *C. R.* 102, 1469).

**Calcium, Seleniocyanide of.** ( $? \text{CaSe}(\text{CN})_2$ ). Probably exists. Data very meagre (Crookes, *J. pr.* 53, 161).

**Calcium, Sulphides of.** One calcium sulphide,  $\text{CaS}$ , is known as a solid; solutions which most probably contain  $\text{CaS}$  and  $\text{CaS}_2$ , respectively, have been prepared. The sulphides of Ca are decidedly less basic than those of Ba, *e.g.* they do not react with the sulphides of the negative metals As and Sb to form thio-salts.

**I. CALCIUM MONOSULPHIDE.**  $\text{CaS}$ . Mol. w. unknown. H.F. solid, from solid materials:  $[\text{Ca}, \text{S}] = 92,000$  (Sabatier, *A. Ch.* [5] 22, 598).

**Preparation.**—1.  $\text{H}_2\text{S}$  is passed over  $\text{CaO.H}_2$  kept at about  $60^\circ$ ; the sole products are  $\text{CaS}$  and  $\text{H}_2\text{O}$ . If the reacting bodies are perfectly dry the change does not occur (Veley, *C. J.* 47, 478).—2. By gently heating crystals of  $\text{CaS.H}_2.6\text{H}_2\text{O}$  (*q.v.*) in  $\text{H}_2\text{S}$ ; the product contains some  $\text{CaO.H}_2$  (Divers a. Shimidzu, *C. J.* 45, 270). Schöne's method, heating  $\text{CaCO}_3$  in a mixture of  $\text{CO}_2$  and  $\text{H}_2\text{S}$  (*P.* 112, 193) is said by Divers to yield a mixture of  $\text{CaS}$  and  $\text{CaO}$  in the ratio  $11\text{CaS}:5\text{CaO}$  (*C. J.* 45, 282).

**Properties and Reactions.**—A white amorphous solid; soluble in water with gradual decomposition, giving  $\text{H}_2\text{S}$ , and solution of  $\text{Ca.SH.OH}$  (*q.v.*) which then slowly decomposes in air forming  $\text{CaS}_2\text{O}_3\text{Aq}$  and  $\text{CaS}_2\text{Aq}$  (Divers a. Shimidzu, *l.c.*). The impure  $\text{CaS}$  produced by heating  $\text{CaO}$  with  $\text{CS}_2$  or  $\text{CaSO}_4$  with C, is not soluble in, although it is partially decomposed by, water. Perfectly dry  $\text{CaS}$  does not absorb  $\text{CS}_2$ ; but in presence of  $\text{H}_2\text{O}$  a basic calcium thiocarbonate,  $2\text{CaO.H}_2.\text{CaCS}_2.10\text{H}_2\text{O}$ , is produced (Veley, *C. J.* 47, 486). Sabatier (*A. Ch.* [5] 22, 698) gives the thermal value  $[\text{Ca}, \text{S}] = 92,000$ ;  $[\text{CaS}, \text{Aq}] = 6,010$  (? pure materials).

**II. CALCIUM POLYSULPHIDES.** When  $\text{CaS}$  (prepared by heating  $\text{CaO}$  in  $\text{CS}_2$  and  $\text{CO}_2$  and therefore containing some  $\text{CaO}$ ) is boiled with S and  $\text{H}_2\text{O}$ , it dissolves, forming an orange-red liquid; the quantity of S which goes into solution corresponds with that required to form  $\text{CaS}_2$  and  $\text{CaS}_3$ ; if more S is used it is deposited on cooling the liquid; if less S than S<sub>2</sub> to  $\text{CaS}$  is used, some of the  $\text{CaS}$  remains undissolved. Both solutions are decomposed on concentration with ppn. of  $\text{CaO.H}_2$  and S, and evolution of  $\text{H}_2\text{S}$  (*v.* Schöne, *P.* 117, 58). Warm  $\text{CaS}_2\text{H}_2\text{Aq}$  dissolves S very readily, forming a solution of  $\text{CaS}_3$  and evolving  $\text{H}_2\text{S}$ ; this solution is completely decomposed (if cold and dilute) by  $\text{H}_2\text{S}$  forming  $\text{CaS}_2\text{H}_2\text{Aq}$  with ppn. of S (Divers a. Shimidzu, *C. J.* 45, 270).

$\text{CaS}_2\text{Aq}$  is decomposed in contact with air. By boiling 8 parts  $\text{CaO}$ , 1 part S, and 20 parts  $\text{H}_2\text{O}$  for some time, and allowing to stand for several days, orange-red needles are obtained of  $8\text{CaO.CaS}_2.12\text{H}_2\text{O}$  (Herschel, *N. Ed. P. J.* 1, 6;

Schöne, *P.* 117, 58),  $2\text{CaO.CaS}_2$ , 10 or 11  $\text{H}_2\text{O}$  according to Geuther (*A.* 224, 178). If  $\text{CaS}$  (prepared by action of  $\text{CS}_2$  and  $\text{CO}_2$  on  $\text{CaO}$ ) is boiled with much water and filtered hot,  $\text{CaSO}_4$  is said to separate out and then yellow needles of  $5\text{CaO.CaS}_2.20\text{H}_2\text{O}$  (*II.* Rose, *P.* 55, 433), or  $4\text{CaO.CaS}_2.18\text{H}_2\text{O}$  (Schöne, *P.* 117, 58), or  $3\text{CaO.CaS}_2$ , 14 or 15  $\text{H}_2\text{O}$  (Geuther, *A.* 224, 178). These oxysulphides are easily decomposed.

**Calcium, Sulphocyanide of.**  $\text{Ca}(\text{CNS})_2$ . By saturating  $\text{HCNSAq}$  with  $\text{CaCO}_3$ , *v.* SULPHOCYANIDES, under CYANIDES.

**Calcium Sulphydrate (or hydrosulphide); and**

**Calcium hydroxy-sulphydrate (or hydroxy-hydrosulphide).**  $\text{CaS.H}_2.6\text{H}_2\text{O}$ , and  $\text{Ca.SH.OH.3H}_2\text{O}$ . By passing  $\text{H}_2\text{S}$  into a solution of  $\text{CaO}$  containing solid  $\text{CaH}_2\text{O}_2$ ,  $\text{CaS}_2\text{H}_2.6\text{H}_2\text{O}$  is formed: 1 part  $\text{CaO}$  is added to 3–4 parts warm water; when cold,  $\text{H}_2\text{S}$  is passed into the semi-solid substance until all has dissolved; more  $\text{CaO}$  is added, little by little, the whole being surrounded by ice, and  $\text{H}_2\text{S}$  is passed in until a little  $\text{CaO}$  remains undissolved; the liquid is quickly decanted into a tube kept in ice; the crystals which separate are drained and a current of dry  $\text{H}_2\text{S}$  is swept over them at  $0^\circ$ . Air must be excluded during the entire operation (Divers a. Shimidzu, *C. J.* 45, 270; Veley, *C. J.* 47, 478).  $\text{CaS}_2\text{H}_2.6\text{H}_2\text{O}$  forms colourless prismatic crystals, which melt in their water of crystallisation, giving off  $\text{H}_2\text{S}$  and forming  $\text{Ca.SH.OHAq}$  and  $\text{CaO}_2\text{H}_2$ . At about  $15^\circ$ – $18^\circ$ ,  $\text{H}_2\text{S}$  is evolved even in an atmosphere of  $\text{H}_2\text{S}$ .  $\text{CaS}_2\text{H}_2.6\text{H}_2\text{O}$  is very soluble in water and alcohol.  $\text{CaS}_2\text{H}_2\text{Aq}$  is slowly oxidised in contact with air, giving a little  $\text{CaS}_2\text{O}_3\text{Aq}$  and  $\text{CaS}_2\text{Aq}$ . Thomson (*Th.* 3, 251) gives the thermal value  $[\text{CaS}_2\text{H}_2\text{Aq}] = 115,250$ .

**References.**—Pelouze, *C. R.* 62, 108; H. Rose, *P.* 55, 133; Berzelius, *S.* 34, 12; P. 6, 442; Böttger, *A.* 29, 79; 33, 344.

When a stream of  $\text{H}_2\text{S}$  is passed through an ice-cold solution of  $\text{CaS}_2\text{H}_2$ , crystals of  $\text{Ca.SH.OH.3H}_2\text{O}$  are formed, and  $\text{H}_2\text{S}$  is evolved. The same compound is formed by the combination of  $\text{H}_2\text{O}$  with  $\text{CaS}$ , as in the interior of heaps of soda-waste; and by the mutual action of  $\text{CaO.H}_2$  and  $\text{H}_2\text{S}$ , as in the purification of coal gas. Calcium hydroxysulphydrate crystallises in colourless four-sided prisms; it is soluble in water with decomposition into  $\text{CaS}_2\text{H}_2\text{Aq}$  and  $\text{CaO.H}_2$ ; insoluble in, but slowly decomposed by, alcohol.  $\text{CaS}_2\text{H}_2$  goes into solution and  $\text{CaO.H}_2$  remains; Divers a. Shimidzu, *C. J.* 45, 270). It absorbs  $\text{CS}_2$  forming a basic thiocarbonate  $2\text{CaO.H}_2.\text{CaCS}_2.10\text{H}_2\text{O}$ ; it is the active agent for absorbing  $\text{CS}_2$  in gas-purification (Veley, *C. J.* 47, 478).

M. M. P. M.

**CALLUTANNIC ACID**  $\text{C}_{12}\text{H}_8\text{O}_6$ . Occurs in *Calluna vulgaris*, the common Ling. The green parts are extracted with alcohol, water is added, and from the filtrate the lead salt is ppd. by  $\text{Pb}(\text{OAc})_2$ . Amber-coloured mass. Its solution in alkalis rapidly absorbs oxygen from the air. Reduces  $\text{AgNO}_3\text{Aq}$ .  $\text{FeCl}_3$  gives a green colour. Dyes mordanted wool sulphur yellow.—

**Salts.**— $(\text{PbC}_{12}\text{H}_8\text{O}_6)_2(\text{PbO})_2\text{aq}(\text{?})$ —  
 $(\text{PbC}_{12}\text{H}_8\text{O}_6)_2(\text{PbO})_2.2\text{aq}(\text{?})$ —  
 $\text{Sn}(\text{C}_{12}\text{H}_8\text{O}_6)_2(\text{SnO}_2).2\text{aq}(\text{?})$ .  
Boiling dilute mineral acids convert callutannic acid into calluxanthin  $\text{C}_{12}\text{H}_8\text{O}_6$ , a yellow floccu-

# CAMPOTANNIC ACID.

lent pp., al. sol. cold water, v. sol. hot water and alcohol. Its alkaline solutions rapidly absorb oxygen from the air (Rochleder, A. 84, 354).

**CALMUS** v. CALAMUS.

**CALOMEL.** Mercurous chloride ( $\text{Hg}_2\text{Cl}_2$ ). V. MERCURY, CHLORIDES OF.

**CALOPHYLLUM RESIN**  $\text{C}_{11}\text{H}_{16}\text{O}_2$ . [ $\alpha$  05°]. S.G. 1.12. A resin from *Calophyllum calaba* or *longifolium* of South America. Said to give butyric acid on oxidation (Levy, C. R. 18, 242).

**CALORIMETER.** Instrument for measuring quantities of heat. V. PHYSICAL METHODS, Sect. THERMAL.

**CALYCIN**  $\text{C}_{18}\text{H}_{12}\text{O}_3$  [240° unc.]. Occurs in a yellow lichen, *Calycium caryosephalum*, from which it is extracted by boiling ligroin (Hesse, B. 13, 1816). Sublimable. Yellow needles or prisms. S. sol. cold petroleum spirit, petroleum ether, ether, alcohol, and acetic acid, more easily in the hot solvents. By strong aqueous KOH it is split up into oxalic and phenyl-acetic acids. Carbonated alkalis give salts of calycic acid.

**CAMELLIN**  $\text{C}_{23}\text{H}_{44}\text{O}_{10}$ . A glucoside occurring in the seeds of *Camellia japonica* (Katuzajama, Ar. Ph. [3] 13, 334). Extracted by alcohol, and p.p.d. by lead acetate. White powder with bitter taste, insol. water. Somewhat resembles digitalin.

**CAMPANIC ACID**  $\text{C}_{10}\text{H}_{14}\text{O}_2$ , i.e.

$\text{C}_6\text{H}_{11}(\text{CO}_2\text{H})\begin{matrix} \diagup \text{O} \\ | \\ \diagdown \text{CO} \end{matrix}$ . Oxy-camphoric anhydride.

From bromo-camphoric anhydride, the product of the action of bromine on camphoric anhydride, by treatment with water (Wroden, A. 163, 330; Woringer, A. 227, 3). From campholic acid and bromine (Kachler, A. 162, 264). Formed also as a by-product in the preparation of camphoric acid by oxidation of camphor with  $\text{HNO}_3$  (Roser, B. 18, 3112). According to Fittig (A. 172, 151) it is a lactonic acid, formed *via*  $\text{C}_6\text{H}_{11}\text{Br}\begin{matrix} \diagup \text{CO} \\ | \\ \diagdown \text{O} \end{matrix}$  and  $\text{C}_6\text{H}_9(\text{OH})(\text{CO}_2\text{H})_2$ .

**Properties.**—Feathery crystals or prisms (from water). Monoclinic,  $a:b:c = 1.2723:1:1.522$ ,  $\beta = 66^\circ 34'$ .

**Salt.**— $\text{BaA}'_2 \cdot 3\text{aq}$

**Reaction.**—1. On distillation campanic acid gives  $\text{CO}_2$ , campholactone  $\text{C}_6\text{H}_{11}\begin{matrix} \diagup \text{O} \\ | \\ \diagdown \text{CO} \end{matrix}$ , and lauro-

nolic acid  $\text{C}_{12}\text{H}_{24}\text{O}_2$ .—2.  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  oxidise it to camphoric acid  $\text{C}_6\text{H}_{10}\text{O}_4$  (Bredt, B. 18, 2989).

**CAMPHENE** v. TERPENES.

**CAMPHENOL** v. BORNEOL and CINEOL.

**CAMPHENYL-p-TOLYL-AMIDINE**

$\text{C}_{17}\text{H}_{19}(\text{NH})\text{NC}_6\text{H}_4$  [115°]. Fine white glistening needles (from ligroin). Formed by heating camphenonitrile  $\text{C}_{17}\text{H}_{17}\text{CN}$  with *p*-toluidine hydrochloride at 250° (Goldschmidt a. Koreff, B. 18, 1633).

**CAMPHIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_2$ . S. 14 at 1°. [ $\alpha$ ]<sub>D</sub> = 15°45' (in alcoholic solution). Formed together with camphoric acid by passing air through a boiling solution of sodium camphor,  $\text{C}_{10}\text{H}_{15}\text{NaO}$  in xylene. Thick mass, v. sol. alcohol and ether.  $\text{KMnO}_4$  oxidises it to camphoric acid. The calcium salt distilled with calcium formate gives camphor and camphrene  $\text{C}_{15}\text{H}_{22}\text{O}$

(c. 288°) (Montgolfier, A. Ch. [3] 14, 70; C. R. 88, 915).

**CAMPHELENE** v. TERPENES.

**CAMPHEMIDE**  $\text{C}_{10}\text{H}_{12}\text{N}$  or  $\text{C}_6\text{H}_9\begin{matrix} \diagup \text{C} \\ | \\ \diagdown \text{NH} \end{matrix}$  (?)

Formed together with dicamphorilimide by distilling the hydrochloride of amido-camphor (v. CAMPHOR) with steam (Schiff, B. 13, 1405).

**CAMPHINE** v. TERPENES.

**CAMPHO-CARBOXYLIC ACID** v. CAMPHOR CARBOXYLIC ACID.

(a) **CAMPHOGLYCURONIC ACID**  $\text{C}_{18}\text{H}_{24}\text{O}_{10}$  [130°]. S. 5. [ $\alpha$ ]<sub>D</sub> = -33°. Occurs, together with uramido-camphoglycuronic acid in the urine of dogs that have taken camphor (Schmiedeknecht a. Meyer, H. 3, 422). Small thin laminae (containing aq); v. c. sol. alcohol and hot water, insol. ether. Boiling dilute HCl splits it up into glycuronic acid  $\text{C}_6\text{H}_{10}\text{O}_6$  and crystalline campherol  $\text{C}_{12}\text{H}_{16}\text{O}_2$  [198°].  $\text{HNO}_3$  oxidises it to camphoric acid.— $\text{BaA}'$  2aq.— $\text{AgHA}'$  2aq.

(b) **Campoglycuronic acid**  $\text{C}_{18}\text{H}_{24}\text{O}_{10}$ . An amorphous modification of the preceding, formed by warming it with baryta.— $\text{AgHA}'$  3aq: crystals, more soluble than the Ag salt of the (a) acid.

**CAMPHOL** a name for BORNEOL (q.v.).

**CAMPHOLACTONE**  $\text{C}_{11}\text{H}_{16}\begin{matrix} \diagup \text{CO} \\ | \\ \diagdown \text{O} \end{matrix}$ . [50°].

(230°-235°). From campanic acid by distillation, together with lauronic acid (Woringer, A. 227, 10). Slender needles (from water). Has a pungent odour of camphor. Like other lactones, its solution becomes cloudy when gently heated, but the oily drops afterwards dissolve up again. Volatile with steam.  $\text{K}_2\text{CO}_3$  separates it from its aqueous solution. When boiled with baryta the salt of the corresponding oxy-acid,  $\text{C}_6\text{H}_{11}(\text{OH})(\text{CO}_2\text{H})_2$ , is formed.

**CAMPHOLENE**  $\text{C}_{11}\text{H}_{16}$  (136°). V.D. 4.35.

Prepared by the action of dehydrating agents on campholic acid (Delalande, A. 38, 310) and by distilling potassium campholate with soda-lime (Kachler, A. 162, 266). Probably identical with the hydrocarbon got by distilling the calcium salt of campholenic acid (Goldschmidt, B. 20, 483). The name campholene has also been given to  $\text{C}_6\text{H}_{11}$  (c. 123°) obtained by the action of dehydrating agents on camphoric acid and its amides (Ballo, B. 12, 324).

**CAMPHOLENIC ACID**  $\text{C}_{10}\text{H}_{14}\text{O}_2$ , i.e.

$\text{C}_6\text{H}_{11}\text{CO}_2\text{H}$  or  $\text{C}_6\text{H}_{11}(\text{CO}_2\text{H})\begin{matrix} \diagup \text{CH}_2 \\ | \\ \diagdown \text{CH}_2 \end{matrix}$ . Oxy-camphor. (c. 260°). Colourless oil. Formed by saponification of its nitrile which is obtained by heating camphoroxim with acetyl chloride. Formed also by treating an alcoholic solution of (8)-dibromo-camphor with sodium-amalgam (Goldschmidt a. Zürer, B. 17, 2069; Kachler a. Spitzer, B. 17, 2400; M. 3, 216; 4, 643). The Ca salt on dry distillation yields  $\text{C}_6\text{H}_{10}$ , possibly campholene (Goldschmidt, B. 20, 483). Oxidising agents give oxy-camphoric acid. At 250° the  $\text{NH}_2$  salt gives the amide [127°].— $\text{NH}_4\text{A}'$ .— $\text{BaA}'_2$  4aq.

**Amide**  $\text{C}_6\text{H}_{11}\text{CONH}_2$ . *Isocamphoroxim* [125°]. Glistening plates; sol. alcohol, ether, and conc. acids. Formed by heating the nitrile with alcoholic KOH, or by heating the ammo-

nium salt of the acid to 250°. By distillation with P<sub>2</sub>S<sub>5</sub> it yields the nitrile (Nägeli, *B.* 17, 805; Goldschmidt a. Zürcher, *B.* 17, 2069).

**Nitrile.**—C<sub>10</sub>H<sub>11</sub>ON. (216°). **Formation.**—1. By heating camphoroxim with AcCl which removes H<sub>2</sub>O.—2. By distilling campholenamide (isocamphoroxim) with P<sub>2</sub>S<sub>5</sub>. **Reactions.**—1. By heating with alcoholic KOH it is converted into campholenamide. By long boiling with alcoholic KOH it yields campholenic acid.—2. By heating with hydroxylamine it gives an amid-oxim C<sub>10</sub>H<sub>11</sub>N<sub>2</sub>O which crystallises in white plates melting at [101°].—3. Reduced in alcoholic solution by Zn and HCl to the amine C<sub>10</sub>H<sub>13</sub>NH<sub>2</sub> (Goldschmidt a. Zürcher, *B.* 17, 2069; Goldschmidt a. Koreff, *B.* 18, 1634).—4. Successive treatment with sodium amalgam and HCl yields C<sub>10</sub>H<sub>13</sub>N<sub>2</sub>Cl<sub>2</sub>, the hydrochloride of camphyl-di-phenyl-hydrazinamine C<sub>10</sub>H<sub>13</sub>(CH<sub>2</sub>NHPh)<sub>2</sub>N<sub>2</sub>Ph. [157°] (Balbiano, *G.* 17, 155).

**Nitro-campholenic acid** C<sub>10</sub>H<sub>13</sub>(NO<sub>2</sub>)O<sub>2</sub>. **Nitro-oxy-camphor** [164°] (Z.); [170°] (K. a. S.). Formed by nitration of campholenic acid (Zürcher, *B.* 18, 2228; Kachler a. Spitzer, *M.* 4, 643; *B.* 15, 2336; Swarts, *B.* 15, 2135). Monoclinic pyramids, *a:b:c* = 76:1:43; β = 89° 18'. Sol. hot alcohol and ether. Reduced by tin and HCl to amido-campholenic acid whose hydrochloride crystallises in laminae [250°].

**CAMPHOLIC ACID** C<sub>10</sub>H<sub>11</sub>O<sub>2</sub>. Mol. w. 170. [95°] (K.); [106°] (M.). [α]<sub>D</sub><sup>20</sup> = 50° (in alcohol).

**Formation.**—1. By passing camphor-vapour over nearly red-hot potash-lime (Delalande, *A. Ch.* [3] 1, 120).—2. By adding potassium in small pieces to a solution of camphor (1 pt.) in boiling petroleum (3 pts.) at 120° (Malin, *A.* 145, 201).—3. By boiling camphor with alcoholic KOH (Kachler, *A.* 162, 250).—4. By heating camphor with Na at 280° (Montgolfier, *A. Ch.* [5] 14, 99).

**Properties.**—Monoclinic prisms (from dilute alcohol) or nodular groups of laminae (from ether-alcohol). V. sl. sol. water; volatile with steam.

**Reactions.**—1. HNO<sub>3</sub> gives first camphoric and then camphoronic acids.—2. Moist Br gives at first camphoric acid, then bromo-camphoric anhydride, and lastly oxy-camphoric anhydride C<sub>10</sub>H<sub>11</sub>O<sub>4</sub>.—3. P<sub>2</sub>O<sub>5</sub> gives campholene; red-hot soda-lime acts similarly.

**Salts.**—KA'2aq: laminar. —CaA'2aq.—AgA'.

**Chloride** (224°) (Kachler, *A.* 162, 265).

**CAMPHOR** C<sub>10</sub>H<sub>16</sub>O. Mol. w. 152. [175°] (204°). S.G. 20° 992. S. 1. S. (alcohol of S.G. 806) 120. V.D. 5.32. R<sub>∞</sub> 76.11 (in a 32.3 p.c. benzene solution) (Kanonnikoff). [α]<sub>D</sub><sup>20</sup> = 55.4—1372 *q* (where *q* = no. of grms. of alcohol in 100 grms. of solution).

Occurs in the wood and bark of *Laurus camphora*, from which it is extracted by distillation with steam followed by sublimation. Varieties of camphor occur also in several essential oils (*v. infra*). Camphor may be recovered from its bromo-derivative by the action of nascent H or of alcoholic KOH (Schiff, *B.* 13, 1407; 14, 1377). Camphor is also formed by distilling calcium camphate with calcium formate and by oxidising dextro- and levo-rotatory borneols (Montgolfier, *C. R.* 88, 915; *A. Ch.* [5] 14, 20).

**Properties.**—Hexagonal prisms, terminated by hexagonal pyramids (Descloizeaux, *A. Ch.* [3] 56, 219; Cazeneuve a. Morel, *C. R.* 101, 438). Tough, with peculiar odour; sublimes at ordinary temperatures. Small pieces rotate upon pure water. V. sl. sol. water, v. sol. ordinary solvents. Camphor is dextro-rotatory, the rotation varying greatly with the nature and strength of the solvent (Arndtsen, *A. Ch.* [3] 54, 403; Landolt, *A.* 189, 334). Its refractive power is that of a saturated compound (Gladstone, *C. J.* 49, 621).

**Reactions.**—1. Camphor (5 kilos.) gives, when oxidised by HNO<sub>3</sub> (1.7 kilos.) pure camphoric acid insol. cold water, and (1.8 kilos.) of crude camphoronic acid. Besides camphoronic acid the soluble portion contains (1 kilo.) of dinitroheptioic acid, and (2 kilo.) of acids C<sub>11</sub>H<sub>11</sub>O<sub>4</sub> (hydro-oxy-camphoronic acid), C<sub>10</sub>H<sub>12</sub>O<sub>4</sub>, C<sub>10</sub>H<sub>12</sub>O<sub>5</sub> (?) [145°], and another acid. A very small quantity (2 g.) of mesocamphoric acid, C<sub>10</sub>H<sub>10</sub>O<sub>4</sub>, is also got. This forms woolly needles, soluble in cold water [120°].—2. By oxidation with CrO<sub>3</sub> it gives camphoronic acid C<sub>10</sub>H<sub>12</sub>O<sub>4</sub> and hydro-oxy-camphoronic acid C<sub>10</sub>H<sub>11</sub>O<sub>4</sub> but not adipic acid (Kachler, *B.* 13, 487; cf. Ballo, *B.* 12, 1597). Alkaline KMnO<sub>4</sub> gives camphoric acid (Grosser, *B.* 14, 2507).—3. The chief products of the dry distillation of camphor with ZnCl<sub>2</sub> (2 pts.) are *m*-methyl-isopropyl-benzene (*m*-cymene) and (1:2:4)-di-methyl-ethyl-benzene (laurene), together with smaller quantities of (1:2:3:5)-tetra-methyl-benzene (isodurene), carvacrol, camphorone, and various other bodies (Armstrong a. Miller, *B.* 16, 2255) such as CH<sub>3</sub>, benzene, toluene, xylene, and *ψ*-cymene (Fittig, *A.* 145, 129; Rommner, *Bl.* 12, 383; Lippmann a. Longuinne, *A.* [2] 5, 413; Montgolfier, *A. Ch.* [5] 14, 87).—4. By the action of iodine it yields a hydrocarbon C<sub>10</sub>H<sub>16</sub>, carvacrol, (1:2:4)-di-methyl-ethyl-benzene, (1:2:3:5)-tetra-methyl-benzene, and traces of ordinary cymene (A. a. M.; cf. Armstrong a. Faskell, *B.* 11, 151; Rayman a. Preis, *B.* 13, 346).—5. By treatment with P<sub>2</sub>O<sub>5</sub> ordinary cymene is formed, which is also the chief product of the action of P<sub>2</sub>S<sub>5</sub> but accompanied in the latter case by small quantities of *m*-methyl-isopropyl-benzene and tetra-methyl-benzene (Delalande, *A. Ch.* [3] 1, 268; Armstrong a. Miller, *B.* 16, 2255).—6. By distillation over red-hot zinc dust a mixture is formed of toluene, *p*-xylene, cymene, and a little benzene (Schrötter, *B.* 13, 1621).—7. Conc. H<sub>2</sub>SO<sub>4</sub> forms camphorone or camphorophorone C<sub>10</sub>H<sub>10</sub>O (Chautard, *C. R.* 44, 66; Schwanert, *A.* 123, 298).—8. Boiling alcoholic KOH forms campholic acid and borneol (Berthelot, *A. Ch.* [3] 56, 94; *J.L.* [2] 17, 390; Montgolfier, *Bl.* [2] 18, 114; 25, 12; Wheeler, *A.* 146, 84; Kachler, *A.* 162, 268). Campholic acid is also formed by passing camphor-vapour over heated soda lime. 9. Cl has no action, but in presence of alcohol or PCl<sub>5</sub> chlorination ensues (Claus, *J.* *pr.* 25, 257).—10. HClO<sub>4</sub> forms chloro-camphor.—11. Br forms C<sub>10</sub>H<sub>15</sub>OBr<sub>2</sub> which readily splits up into HBr and bromo-camphor.—12. ICl at 250° forms CCl<sub>4</sub>, C<sub>2</sub>Cl<sub>4</sub>, and C<sub>3</sub>Cl<sub>4</sub>.—13. PCl<sub>5</sub> forms C<sub>10</sub>H<sub>11</sub>Cl<sub>2</sub>.—14. Camphor absorbs HCl (Binéau, *A. Ch.* [3] 24, 328). Aqueous HCl at 170°

splits it up into  $H_2O$  and cymene (Alexejeff, *J. R.* 12, 187).—15. Camphor absorbs  $SO_2$ , becoming liquid.—16. It also absorbs  $NO_2$ .—17. Conc.  $HIAg$  at  $200^\circ$  forms  $C_{10}H_{16}$  ( $163^\circ$ ),  $C_8H_{14}$  ( $135^\circ-140^\circ$ ), and  $C_{10}H_{20}$  ( $170^\circ-175^\circ$ ) (Weyl, *Z.* [2] 4, 496; *B.* 1, 96).—18. *Sodium-amalgam* has no action.—19.  $Na$  acting at  $90^\circ$  on a solution of camphor in toluene forms sodium-camphor and sodium borneol (Baubigny, *Z.* [2] 2, 408; 4, 298) (cf. p. 672).—20.  $CO_2$  gas passed into the product of the action of  $Na$  on camphor in toluene forms the carboxylic acids of camphor and of borneol (Baubigny, *Z.* [2] 4, 482, 647). Air passed into the same mixture forms camphoric acid (Montgolfier, *A. Ch.* [5] 14, 75).—21. Camphor does not combine with  $NaHSO_3$  (Fittig a. Tollens, *A.* 129, 371).—22.  $AcCl$  has no action.—23. Converted in the animal economy (of a dog) into camphoglycuronic acid (*q. v.*).—24. Melted camphor absorbs  $BF_3$  forming  $C_{10}H_{16}OBF_3$  [ $70^\circ$ ]; when this is heated for 24 hours there is formed cymene and its polymerides,  $C_{10}H_{16}$ ,  $C_8H_{12}$ , and other hydrocarbons (Landolph, *C. R.* 86, 539).—25. *Chloral hydrate* forms an unstable molecular compound with camphor. It is a viscous liquid, sol. alcohol and  $CHCl_3$ , insol. water (Cazeneuve a. Imbert, *Bl.* [2] 34, 209; Zeidler, *J.* 1878, 645).—26. By heating with *ammonium formate* at  $220^\circ-240^\circ$  it yields formyl-bornylamine

104).—27. It does not react with phenyl-cyanate (*L. a. B.*).—28. Hydroxylamine forms an oxim, *v.* CAMPHOROXIM.

*Phenyl-hydrazide*  $C_{10}H_{16}N_2HPh$ . ( $233^\circ$ ) at 10 mm. From camphor and phenyl-hydrazine. Oil. Split up by dilute  $HCl$  into camphor and phenyl-hydrazine, acid by dry  $HCl$  into aniline and the nitrile of campholenic acid (Balbiano, *G.* 16, 132).

*Constitution.*—The action of hydroxylamine on camphor coupled with the fact that camphor does not combine with  $NaHSO_3$  indicates that it is a ketone. The ready formation of benzene derivatives indicates a six-carbon ring. Its optical properties are those of a saturated compound, *v.* also TERPENES.

The two following formulæ amongst others have been proposed for camphor:

nikoff, *J. pr.* [2] 32, 511; cf. Kekulé, *B.* 6, 931);

*Chloro-camphor*  $C_{10}H_{15}ClO$ . [ $95^\circ$ ]. From camphor and conc.  $HClO_4$  (Wheeler, *Am. S.* [2] 45, 48; *A.* 146, 81). Crystalline powder (from alcohol); at  $200^\circ$  it gives off  $HCl$ . Decomposed by alcoholic  $AgNO_3$ .

( $\alpha$ )-Chloro-camphor  $C_{10}H_{15}ClO$ . [ $84^\circ$ ]. (*C.*); [ $93^\circ$ ] (*B.*). ( $246^\circ$ ). [ $\alpha$ ]<sub>D</sub> =  $90^\circ$ . Formed by passing dry  $Cl$  into a solution of camphor (760g.) in absolute alcohol (230g.) (Cazeneuve, *C. R.* 94, 1530; *Bl.* [2] 38, 9; 44, 161). Formed also by heating chloro-camphor carboxylic acid (Schiff a. Puliti, *B.* 16, 887; Balbiano, *G.* 17, 95). Hard, brittle,

monoclinic needles; smelling like camphor; volatile with steam. Not decomposed by alcoholic  $AgNO_3$ . Sodium-amalgam reduces it to camphor; the copper-zinc couple, and hot soda-lime, act similarly. Alcoholic  $KOH$  at  $180^\circ$  gives borneol. Phenyl-hydrazine forms  $C_{10}H_{15}(N_2HPh)(N_2Ph_2)$  [ $56^\circ$ ] (*B.*).

( $\beta$ )-Chloro-camphor  $C_{10}H_{15}ClO$ . [ $100^\circ$ ]. ( $246^\circ$ ). [ $\alpha$ ]<sub>D</sub> =  $57^\circ$ . Deposited from the mother-liquor after the preceding has separated (Cazeneuve, *C. R.* 95, 1358; *Bl.* [2] 39, 116). Soft, minute, needles, more soluble than the preceding; miscible with boiling alcohol. Not decomposed by alcoholic  $AgNO_3$ , but converted by boiling alcoholic  $KOH$  into the preceding body. Phenyl-hydrazine produces the same compound [ $56^\circ$ ] as with the preceding (*B.*).

( $\alpha$ )-Di-chloro-camphor  $C_{10}H_{13}Cl_2O$ . [ $96^\circ$ ]. *S. G.* 4.2. [ $\alpha$ ]<sub>D</sub> =  $57.3^\circ$  (in alcohol or chloroform). Formed by passing dry chlorine for several hours into camphor dissolved in absolute alcohol at  $80^\circ-90^\circ$ . The product is ppd. by water and crystallised from alcohol (Cazeneuve, *C. R.* 94, 730, 1058; *Bl.* [2] 37, 454). Trimetric prisms (from alcohol); *a:b:c* =  $1.8358:1.14820$ ; sl. sol. cold, v. sol. hot, alcohol; almost insol. water but rotates upon it. Above  $150^\circ$  it blackens, giving off  $HCl$ . Insol.  $HOAc$  (difference from camphor). It forms a liquid combination with aldehyde.

( $\beta$ )-Di-chloro-camphor  $C_{10}H_{13}Cl_2O$ . [ $77^\circ$ ]. [ $\alpha$ ]<sub>D</sub> =  $57.4^\circ$  (in alcohol);  $60.6^\circ$  (in  $CHCl_3$ ). Ppd. by adding water to the mother-liquor from which the preceding has crystallised (Cazeneuve, *C. R.* 94, 1360; *Bl.* [2] 38, 8). Crystallises from alcohol with difficulty; v. sol. alcohol, ether, and chloroform; liquefied by chloral-hydrate (difference from the preceding).

Tri-chloro-camphor  $C_{10}H_{11}Cl_3O$ . [ $54^\circ$ ]. [ $\alpha$ ]<sub>D</sub> =  $64^\circ$  (in alcohol). Formed by saturating chloro-camphor with chlorine at  $100^\circ$  (Cazeneuve, *C. R.* 99, 609). Minute crystals, insol. water, sol. other menstrua. Gives off  $HCl$  when heated.

Bromo-camphor  $C_{10}H_{15}BrO$ . [ $76^\circ$ ]. ( $274^\circ$ ). *S. G.* 1.44  $R_D$  88.5 (in a 7.37 p.c. alcoholic solution) (Kanonnikoff, *J. pr.* [2] 32, 504). [ $\alpha$ ]<sub>D</sub> =  $139^\circ$ . Formed by heating camphor dibromide at  $100^\circ$  (Perkin, *C. J.* 18, 92; Maisch, *C. C.* 1873, 437). Monoclinic prisms (from alcohol); m. sol. alcohol, v. sol.  $CHCl_3$  and benzene; may be sublimed (Montgolfier, *Bl.* [2] 23, 253).

*Reactions.*—1. *Sodium-amalgam* reduces it, in alcoholic solution, to camphor; alcoholic  $KOH$  also gives camphor. Sodium added to its solution in toluene gives sodium camphor (R. Schiff, *B.* 13, 1407).—2.  $PCl_5$  has no action even at  $100^\circ$  (Schiff, *B.* 14, 1378; Kachler a. Spitzer, *M.* 3, 205).—3. Heating with  $ZnCl_2$  at  $160^\circ$  gives a mixture of *p*-xylene hexahydride and a phenol  $C_{10}H_8O$  apparently identical with the carvacrol obtained by the action of  $I$  on camphor (R. Schiff, *B.* 13, 1407).—4. *Nitric acid* forms bromo-nitro-camphor and camphoric acid (Armstrong, *B.* 12, 1358; R. Schiff a. Maisson, *C.* 10, 317).—5. *Phenyl-hydrazine* forms  $C_{10}H_{15}(N_2HPh)(N_2Ph_2)$ , [ $56^\circ$ ] (Balbiano, *G.* 17, 95, 155).

( $\alpha$ )-Di-bromo-camphor  $C_{10}H_{13}Br_2O$ . [ $115^\circ$ ]. Formed, together with the preceding, by heating bromo-camphor (1 mol.) with  $Br$  (2 mols.) for 11

hours at 180° (Kra. S.; cf. Swarts, *Z.* [2] 2, 205; *B.* 15, 1622). Formed also by heating (β)-di-bromo-camphor with gaseous HBr at 180° (Swarts, *B.* 15, 2135). Trimetric crystals; *a:b:c* = 95:1:52; sl. sol. alcohol, ether, and petroleum. Less volatile with steam than the preceding.

**Reactions.**—1. Sodium-amalgam gives camphor and campholenic acid.—2. Conc. HNO<sub>3</sub> gives di-bromo-nitro-camphor [130°].

(β)-Di-bromo-camphor C<sub>10</sub>H<sub>16</sub>Br<sub>2</sub>O. [61°]. Formed, together with its isomeride, by the action of Br (1 mol.) on bromo-camphor (1 mol.) for 7 hours at 120° (Kachler a. Spitzer, *M.* 3, 208; Zepharovich, *M.* 3, 231; cf. R. Schiff, *G.* 11, 178; Morfoggier, *Bl.* [2] 23, 253). Trimetric crystals, *a:b:c* = 2.0685:1:1.5778 (Cazeneuve a. Morel, *Bl.* [2] 44, 161) = 1.944:1:1.558 (K. a. S.). V. sol. alcohol, ether, and petroleum.

**Reactions.**—1. Alcoholic KOH, or sodium-amalgam, reduces it to bromo-camphor, and finally to camphor.—2. Sodium and CO<sub>2</sub> form camphor carboxylic acid.—3. Conc. HNO<sub>3</sub> gives camphoric, and hydro-oxy-camphoric, acids, together with bromo-di-nitro-methane (Kachler a. Spitzer, *M.* 4, 554).

(α)-Chloro-bromo-camphor C<sub>10</sub>H<sub>15</sub>ClBrO. [98°]. [α]<sub>D</sub> = 78°. Formed by heating chloro-camphor [81°] with bromine in sealed tubes for 5 hours at 100°. White needles. Insol. water, sol. hot alcohol, ether, and CHCl<sub>3</sub> (Cazeneuve, *Bl.* [2] 44, 115; *C. R.* 100, 802).

(β)-Chloro-bromo-camphor C<sub>10</sub>H<sub>15</sub>ClBrO. [51.5°]. [α]<sub>D</sub> = 51°. Prepared by heating chloro-camphor (1 mol.) with bromine (2 mols.) in sealed tubes for one hour at 100° C. Hard, trimetric crystals, *a:b:c* = 1.914:1:1.5395. Insol. water, v. sol. alcohol, v. sol. conc. CHCl<sub>3</sub>, C<sub>6</sub>H<sub>6</sub>, and CS<sub>2</sub> (Cazeneuve, *Bl.* [2] 44, 115; *C. R.* 100, 853). Decomposed by heating AgOAcAg (difference from preceding).

Iodo-camphor C<sub>10</sub>H<sub>15</sub>IO. [44°]. Formed, together with NaCy and NaI, by the action of ICy on sodium-borneol dissolved in benzene (Haller, *C. R.* 87, 635). Monoclinic crystals, insol. water, sol. alcohol. Decomposes at about 150°.

Nitro-camphor C<sub>10</sub>H<sub>15</sub>NO<sub>2</sub>. [83°]. Prepared by the action of alcoholic KOH on bromo-nitro-camphor (Schiff, *B.* 13, 1402; *G.* 10, 330; 11, 21). Dissolves in aqueous alkalis. Gives a red colouration with FeCl<sub>3</sub>. HNO<sub>3</sub> gives a nitroso-compound. On oxidation with HNO<sub>3</sub> it gives camphoric acid. By reduction it gives: amido-camphor. Bromine forms C<sub>10</sub>H<sub>15</sub>NBrO<sub>2</sub>? [95°]. Cl forms similarly C<sub>10</sub>H<sub>15</sub>NClO<sub>2</sub>? [110°]. Steam-distillation gives camphoric acid and anhydride and NH<sub>3</sub>. This substance is probably a mixture of the two following.

(α)-Nitro-camphor C<sub>10</sub>H<sub>15</sub>(NO<sub>2</sub>)O. [101°]. [α]<sub>D</sub> (19.978 p.c. in benzene) = -98°; (3.33 p.c. in alcohol) = -7.5°. Formed, together with its (β)-isomeride, by the action of Zn, Cu, Fe, or alkalis on either chloro-nitro-camphor dissolved in alcohol. Best prepared by using the copper-zinc couple. The resulting zinc-salt of nitro-camphor is decomposed by HCl. The (α)-compound is the less soluble in cold alcohol (Cazeneuve, *C. R.* 103, 275; 104, 1522; *Bl.* [2] 47, 920). Trimetric prisms. Decomposes at 160°. Levorotatory. Its rotation varies with concentration of the solution. It forms a com-

pound with benzene. It reddens litmus, and decomposes carbonates. FeCl<sub>3</sub> colours its alcoholic solution blood-red.

(β)-Nitro-camphor C<sub>10</sub>H<sub>15</sub>(NO<sub>2</sub>)O. [98°]. [α]<sub>D</sub> (3.33 p.c. in benzene) = -75°; (3.33 p.c. in alcohol) = +7.5°. Prepared as above. Soft, fern-like, crystals (from alcohol). Insol. water, sol. other menstrua. Less stable than the (α)-isomeride. FeCl<sub>3</sub> colours its solutions red. Its salts are more soluble than those of the (α)-compound.—NaA':—ZnA': sol. water.

(α)-Chloro-nitro-camphor C<sub>10</sub>H<sub>15</sub>Cl(NO<sub>2</sub>)O. [95°]. [α]<sub>D</sub> = -6.2°. From chloro-camphor [92°] (1 pt.) and fuming HNO<sub>3</sub> (4 pts.). Large trimetric prisms (from alcohol); *a:b:c* = 2.022:1:1.475 (the author does not say whether these numbers belong to this or to the following body). Insol. water, m. sol. cold alcohol. Decomposes above 100°. Reduced by nascent hydrogen to nitro-camphor (Cazeneuve, *C. R.* 96, 589; *Bl.* [2] 39, 503).

(β)-Chloro-nitro-camphor C<sub>10</sub>H<sub>15</sub>Cl(NO<sub>2</sub>)O. [98°]. [α]<sub>D</sub> = 10.5° (in alcohol). Occurs in the mother-liquor from which the preceding has separated. Soft crystals, v. sol. cold alcohol. Reduction gives nitro-camphor. Less stable than the (α)-isomeride, for alkalis remove Cl forming nitro-camphor even in the cold. Not decomposed by alcoholic AgNO<sub>3</sub> (Cazeneuve, *C. R.* 98, 306; *Bl.* [2] 41, 285; 44, 161; 47, 926).

(γ)-Bromo-nitro-camphor C<sub>10</sub>H<sub>15</sub>BrNO<sub>2</sub>. [105°]. [α]<sub>D</sub> = -27°. Prepared by nitration of bromo-camphor. Trimetric crystals, *a:b:c* = 2.0854:1:1.5423. Nearly insol. cold alcohol. By the action of alcoholic KOH or nascent H it gives nitro-camphor (Schiff, *G.* 10, 324; *B.* 13, 1402; 14, 1377).

Di-bromo-nitro-camphor C<sub>10</sub>H<sub>15</sub>Br(NO<sub>2</sub>)O. [130°]. From (γ)-di-bromo-camphor by nitration (Kachler a. Spitzer, *M.* 4, 554). Trimetric prisms or needles, *a:b:c* = 1.76:1:1.49. Reduced by tin and HIOAc to amido-camphor.

Amido-camphor C<sub>10</sub>H<sub>15</sub>NO. (217°). Waxy solid. Strong base of alkaline reaction. Prepared by reduction of nitro-camphor with sodium-amalgam in alkaline solution. It reduces Fehling's solution, AgNO<sub>3</sub>, and HgCl<sub>2</sub>. With HNO<sub>3</sub> it produces oxy-camphor (Schiff, *B.* 13, 1404). On distillation of the hydrochloride of amido-camphor with steam, 'dicamphylamine' C<sub>20</sub>H<sub>31</sub>NO<sub>2</sub> passes over and 'camphimide' C<sub>10</sub>H<sub>15</sub>N remains in the retort. Dicamphylamine [160°] crystallises in needles, insol. acids, volatile with steam. Camphimide forms crystalline flakes, soluble in acids; nitrous acid converts its hydrochloride into 'diazo-camphor' C<sub>10</sub>H<sub>15</sub>N<sub>2</sub>O [74°] which may be reduced by Zn and HIOAc to amido-camphor. Diazo-camphor is converted by heat into 'dehydro-camphor' C<sub>10</sub>H<sub>15</sub>O [160°] (*R.* Schiff, *G.* 10, 362; 11, 171; *B.* 14, 1375).

Oxy-camphor (?) C<sub>10</sub>H<sub>15</sub>O<sub>2</sub> [155°]. Prepared by the action of HNO<sub>3</sub> on amido-camphor (Schiff, *B.* 13, 1404). Colourless crystals. Volatile with steam.

Wheeler's chloro-camphor (*q.v.*) gave with alcoholic KOH an 'oxy-camphor' [137°].

The acetyl derivative [69°] of an 'oxy-camphor' [249°] is formed by oxidising acetyl-borneol.

An 'oxy-camphor' [61°] is formed by oxidising camphene (v. TERPENES) (Kachler a. Spitzer, A. 200, 358).

V. also CAMPHOLENIC ACID.

'Nitro-oxy-camphor,' v. NITRO-CAMPHOLENIC ACID.

Cyano-camphor v. NITRILE of CAMPHOR CARBOXYLIC ACID.

Ethyl-camphor  $C_{10}H_{18}EtO$ . (228°). S.G. 22.946.  $[a]_D = 161^\circ$ . From sodium-camphor and EtI (Baubigny, Z. [2] 4, 481). Oil.

Isoamyl-camphor  $C_{10}H_{18}(C_4H_9)O$ . (278° cor.).  $[a]_D = 59.4^\circ$ . From sodium-camphor and isoamyl iodide (B.).

'Nitrohexoic acid'  $C_6H_7(NO_2)_2O_2$ , i.e.  $Me.CH(NO_2).CMe_2.CO_2H(?)$  [115°]. From dinitro-heptoic acid and sodium-amalgam (Kullhem, A. 167, 45; Kachler, A. 191, 157). Rectangular four-sided columns (from water). Monoclinic;  $b:c = 1.6115$ ;  $\beta = 83^\circ 30'$ . After several fusions it melts at  $111.5^\circ$ . Quickly heated, it explodes.

Reactions.—1. Dissolved in a little aqueous KOH, mixed with  $KNO_3$  and dilute  $H_2SO_4$ , a fine blue colour is formed. This colour is taken up by ether; hence the body is probably akin to pseudo-nitroles.—2. Sn and HCl produce methyl-isopropyl ketone, hydroxylamine, and  $CO_2$ .—3. Baryta in sealed tubes at  $95^\circ$  does not decompose it, but forms the basic salt  $C_6H_7BaNO_4$ .

Dinitrohexoic acid  $C_6H_7(NO_2)_2O_2$ , i.e.  $MeC(N_2O_2).CMe_2.CO_2H(?)$  [125°]. Got by Kullhem by treating the residues in the preparation of camphoric acid with strong  $HNO_3$  (A. 163, 231; Kachler, A. 191, 155). Monoclinic plates;  $a:b:c = .5735:1: .6024$ ;  $\beta = 70^\circ 42'$ . M. sol. cold water, v. sol. hot water. Explodes when rapidly heated. Its ammonium salt gives with cupric acetate a bluish pp. sol. excess of the acetate (difference from camphoric acid). The free acid does not pp. cupric or lead acetate. The neutral salts give a flocculent pp. with lead acetate.

Salt.— $BaA'2$  3aq. Needles.

Reactions.—1. Reduced in alcoholic solution by sodium amalgam to mononitroheptoic acid. 2. Reduced by Sn and HCl to methyl iso-propyl ketone and hydroxylamine.—3. Potash and baryta heated with the aqueous acid in sealed tubes produce both nitro-heptoic acid and methyl isopropyl ketone.

Hydro-oxy-camphoric acid  $C_{10}H_{14}O_6$  [164.5°] (Kachler, A. 191, 148). Needles. Sol. cold water. Tribasic acid. Gives no pp. with  $BaCl_2$  or  $CaCl_2$  and  $NH_3$ , even on boiling (difference from camphoric acid). Cupric acetate gives no pp. until boiled when a bluish-green cupric salt is p.p.d. Lead acetate gives a white pp. soluble in excess.  $AgNO_3$  gives a white pp. soluble in hot water.

Salts.— $NH_4A'''$ ,  $-CaHA'''$  2aq.— $Ca_2A'''$ ,  $-Ba_2A'''$ ,  $-Cu_2A'''$ ,  $-Ag_3A'''$ .

#### ISOMERIDES OF CAMPHOR.

Lævorotatory camphor  $C_{10}H_{16}O$ . [172° cor.] (R.); [175°] (C.). (204°). S.G. 22.9853 (C.).  $[a]_D = -47^\circ$  (C.);  $-42^\circ$  (H.). Occurs together with a terpene in the ethereal oil obtained from the leaves of fever-few, *Matricaria Parthenium* (Chautard, C. R. 87, 166). Apparently formed also by oxidising the lævorotatory terpene obtained by treating with alcoholic KOH the pro-

duct of the action of HCl on lævorotatory oil of turpentine (Riban, Bl. 24, 19). Obtained also by oxidising the borneols of madder, valerian, Ngai, and Bang-Phien (Haller, C. R. 108, 64; 104, 66).  $HNO_3$  gives lævorotatory camphoric acid  $[a]_D = -46^\circ$ . The corresponding bromo-camphor is also lævorotatory,  $[a]_D = -128^\circ$ .

Inactive camphor  $C_{10}H_{16}O$ . [173°]. Got by oxidising inactive borneol (q. v.) with cold  $HNO_3$ , and then adding water (Armstrong a. Tilden, C. J. 35, 752). Also by oxidising inactive camphene with  $H_2SO_4$  and  $K_2Cr_2O_7$ . Heated with  $HNO_3$  it forms a camphoric acid, [203°] and giving when heated alone an anhydride, [223°].

Inactive camphor From Oil of Sage.  $C_{10}H_{16}O$ . [174°]. (205° uncor.). When oil of sage is distilled, the fraction 205°–208° deposits this camphor. It apparently only differs from ordinary camphor in being inactive, for:—1. PCl, gives an oil which is converted by water into a wax-like solid, [80°] whence Na forms a white solid.—2. Boiled with  $HNO_3$  (2:1) it forms inactive camphoric acid [186°].—3. Dissolved in toluene and treated with Na and  $CO_2$ , it forms inactive borneol, [200°].—4. Distilled with  $P_2S_5$ , it forms cymene (M. M. P. Muir, C. J. 37, 685).

'Racemic' camphor  $C_{10}H_{16}O$  (?). [179°]. This name is given to the product of the oxidation of a mixture of equivalent quantities of lævo- and dextro- rotatory borneol, and is therefore inactive by compensation, as racemic acid is (Haller, C. R. 105, 66). It gives a bromo-derivative [51°] and a camphoric acid [205°]. The 'racemic' camphor, bromo-camphor, and camphoric acid were also prepared by mixture and found to be identical with the above. They differ in solubility as well as in melting-point from the active compounds. The borneol of amber, and consequently the camphor derived therefrom, appear to be a mixture of dextro- and lævo-rotatory varieties in unequal proportions.

Camphors, or bodies resembling camphor, have been found in many essential oils, e.g. oils of alant (p. 94), absinth (p. 2), chamomile, eucalyptus, lavender, nutmeg, rosemary, &c. When a camphor is converted into borneol, the rotatory power of the resulting borneol varies with each operation, but the camphor regenerated by oxidising the borneol has in each case the rotatory power of the original camphor (Montgolfier). According to Haller (C. R. 105, 228) this may be explained by supposing that the resulting borneol is always a mixture of a stable borneol rotating in the same direction as the original camphor and of an unstable borneol rotating in the opposite direction.

CAMPHOR-CARBOXYLIC ACID  $C_{11}H_{16}O_5$ . [129°]. Formed as a by-product in the preparation of borneol from camphor by the action of Na on a solution of camphor in toluene, the product being treated with  $CO_2$ . It is produced by the union of  $CO_2$  with sodium-camphor (Baubigny, Z. [2] 4, 481, 647; A. Ch. [4] 19, 221; Kachler a. Spitzer, B. 18, 1412; M. 2, 233). Long colourless monoclinic pyramids. Sol. water. Decomposes below  $100^\circ$  into  $CO_2$  and camphor.

Reactions.—1. Boiling AcCl forms  $C_{12}H_{20}O_4$  [196°], crystallising in needles.—2.  $P_2O_5$ , acting

on its solution in  $\text{CHCl}_3$ , forms  $\text{C}_{10}\text{H}_{16}\text{O}_4$ . [265°].  
8.  $\text{PCl}_5$  forms  $\text{C}_{10}\text{H}_{14}\text{O}_4$ . [45°] which separates from ether-alcohol in triclinic crystals  $a:b:c = 1:804:47$ .

**Salts.**— $\text{NaA}'$ .— $\text{BaA}'$ .— $\text{PbA}'$ .

**Ethyl ether EtA'**: (276° uncor.); S.G. 1.1052; colourless fluid (Roser, B. 18, 8118).

**Nitrile  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}$ . Cyano-camphor.** [128°]. (250°). Formed by passing cyanogen into a mixture of camphor and sodium-camphor dissolved in hot toluene; extracted by shaking with aqueous NaOH and ppg. by HOAc. Rectangular prisms (from ether); sol. alcohol, ether, and HOAc. Contains an atom of hydrogen displaceable by Na or K, forming unstable salts. Conc. HCl at 100° converts it into camphor carboxylic acid. Oxidising agents give IICy and camphoric acid. Alcoholic NaOH slowly converts it into the ether of camphor carboxylic acid (Haller, C. R. 87, 843; 93, 72; 102, 1477).

**Chloro-camphor carboxylic acid  $\text{C}_{10}\text{H}_{13}\text{ClO}_4$ .** Formed by passing Cl into a solution of sodium camphor carboxylate (Schiff, A. Paliti, B. 16, 887). Flocculent pp.; decomposes on fusion into  $\text{CO}_2$  and chloro-camphor.

**Bromo-camphor carboxylic acid  $\text{C}_{10}\text{H}_{13}\text{BrO}_4$ .** [110°]. From camphor carboxylic acid and Br (Silva, B. 6, 1093). Both the acid and its salts readily decompose into  $\text{CO}_2$  and bromo-camphor.— $\text{BaA}'$ .— $\text{AgA}'$ .

**Oxy-camphor carboxylic acid  $\text{C}_{10}\text{H}_{11}\text{O}_5$ .** [160°].  $[\alpha]_D = 59^\circ$ . Formed by boiling the nitrile of camphor carboxylic acid with aqueous KOH (Haller, C. R. 87, 929). Nodules (from ether).— $\text{CaA}'$  6aq.— $\text{BaA}'$  6aq.

**CAMPHOR DICHLORIDE  $\text{C}_{10}\text{H}_8\text{Cl}_2$ .** [155°]. Prepared by the action of  $\text{PCl}_5$  on camphor in the acid:  $\text{C}_{10}\text{H}_{16}\text{O} + \text{PCl}_5 = \text{POCl}_3 + \text{C}_{10}\text{H}_8\text{Cl}_2$  (Spitzer, B. 11, 363, 1819; M. 1, 319). Formed also by chlorinating bornyl chloride (Brunner, A. Spitzer, A. 200, 361). Feathery trimetric needles;  $a:b:c = 917:11:686$ . Easily soluble in alcohol and ether. Easily splits off HCl.

**CAMPHORIC ACID  $\text{C}_{10}\text{H}_{16}\text{O}_4$  i.e.**

$\text{CH}_2 - \text{CPr} - \text{CO}_2\text{H}$  (Schiff)  
 $\text{C}_6\text{H}_{11}(\text{CO}_2\text{H})_2$  or  $\text{CH}_2 - \text{CMe} - \text{CO}_2\text{H}$

or  $\text{Pr.CH}(\text{CO}_2\text{H}).\text{CH}_2.\text{CH}(\text{CMe.CO}_2\text{H})$  (W. Roser, A. 220, 278). Mol. w. 200. [186°]. S.G. 1.19. S. 625 at 12°. R. 83-14 (in a 1 p.c. aqueous solution) (Kannonnikoff, J. pr. [2] 34, 349).  $[\alpha]_D = 46^\circ$ . Formed by boiling camphor or campholic acid with conc.  $\text{HNO}_3$  (Kosegarten (1785); Laurent, A. Ch. 63, 207; Malaguti, A. Ch. 64, 151; A. 22, 50; Wreden, A. 163, 323; V. Meyer, B. 3, 116; Kachler, A. 162, 262). It is best to use the mixture of camphor and bornol obtained by the action of Na on camphor (Maissen, G. 10, 280). Formed also by the oxidation of chloro- or bromo-camphor with alkaline permanganate (Balbiano, G. 17, 240). Monoclinic crystals; the rotation in alkaline solution has been studied by Thomsen (J. pr. [2] 35, 157). The refractive power indicates a double union, which does not agree with Schiff's formula.

**Reactions.**—1. Heat splits it up into water and an anhydride.—2. Water at 180° changes it into meso-camphoric acid.—3. Fuming HCl at 200° forms  $\text{C}_6\text{H}_{11}$  and  $\text{C}_4\text{H}_7$  (Wreden, A. 187, 169).—4. Conc.  $\text{HClAq}$  at 200° gives xylene tetra-

hydride and hexahydride (W.).—5. By the action of  $\text{ZnCl}_2$ , xylene tetrahydride  $\text{C}_6\text{H}_8$ , is produced:  $\text{C}_6\text{H}_{11}(\text{CO}_2\text{H})_2 = \text{C}_6\text{H}_8 + \text{CO}_2 + \text{CO} + \text{H}_2\text{O}$ .

The same hydrocarbon is produced by the action of  $\text{ZnCl}_2$  on ammonium camphoric acid:  $\text{C}_{10}\text{H}_{16}\text{O}_4(\text{NH}_4)(\text{ONH}_4) + \text{ZnCl}_2 + \text{H}_2\text{O} =$

$2\text{NH}_4\text{Cl} + \text{ZnO} + \text{CO} + \text{CO}_2 + \text{C}_6\text{H}_8$  (Ballo, B. 12, 324).—6. The ammonium salt distilled with  $\text{P}_2\text{O}_5$  gives a terpene  $\text{C}_{10}\text{H}_{16}$  (Ballo, A. 197, 324).

7. Conc.  $\text{H}_2\text{SO}_4$  forms CO and 'sulphocamphoric acid'.—8. Conc.  $\text{HNO}_3$  gives camphoric acid.—9. Potash-fusion gives pimelic acid  $\text{Pr.CH}(\text{CO}_2\text{H}).\text{CH}_2.\text{CO}_2\text{H}$  and an acid  $\text{C}_{16}\text{H}_{16}\text{O}_8$  (Illasiwetz a. Grabowsky, A. 145, 205).—10. Distillation with soda-lime gives camphoric anhydride and phorone  $\text{C}_{10}\text{H}_{14}\text{O}$  (Meyer, B. 3, 117). Distillation of camphorates gives similar results.

**Salts.**—(Viemper, Ar. Ph. [2] 110, 106; 117, 23).  $\text{NH}_4\text{HA}'$  2aq.— $(\text{NH}_4)_2\text{A}'$ .— $\text{Li}_2\text{A}'$ .— $\text{Na}_2\text{A}'$ .— $\text{K}_2\text{A}'$ : deliquescent.— $\text{MgA}'$  7aq. S. 40 at 20°.— $\text{MgA}'$  12aq.— $\text{MgA}'$  13aq.— $\text{CaHA}'$ .— $\text{CaA}'$  4aq.— $\text{CaA}'$  7aq.— $\text{Ca}_2\text{A}'$  8aq.— $\text{BaHA}'$  2aq.— $\text{BaA}'$  2aq.: needles and feathers (Kingzett, C. J. 45, 93).— $\text{BaA}'$  4aq.— $\text{ZnA}'$ .— $\text{PbA}'$ .— $\text{CuA}'$ .— $\text{Ag}_2\text{A}'$ .

**Ethyl-ammonium salt  $(\text{NH}_4\text{Et})_2\text{A}'$ :** small needles (from alcohol). Converted by  $\text{PCl}_5$  into camphoric di-ethyl-imidine.

**Mono-methyl ether MeHA'**. [68°].  $[\alpha]_D = 51.4^\circ$ . Trimetric prisms (from ether); gives camphoric anhydride when distilled. V. sl. sol. water (Loir, A. Ch. [3] 38, 483).

**Mono-ethyl ether EtHA'**. S.G. 1.095. Syrup.

**Di-ethyl ether Et<sub>2</sub>A'**. (286°). S.G. 1.029. Formed, together with camphoric anhydride, by the distillation of the mono-ethyl ether (Malaguti, A. Ch. [3] 64, 152; 70, 360; Meyer, B. 3, 118). Liquid  $\text{C}_6\text{H}_8$  produces a tetrachloro-derivative  $(\text{C}_6\text{H}_3\text{Cl}_4)_2\text{A}'$ . S.G. 1.386.

**Chloride  $\text{C}_{10}\text{H}_8\text{O}_4\text{Cl}_2$ .** Heavy oil, decomposing at 200° (Moitessier, A. 120, 352).

**Anhydride  $\text{C}_{10}\text{H}_{14}\text{O}_3$ .** [217°]. (above 270°). S.G. 1.194.  $[\alpha]_D = -7.7^\circ$  (in benzene).

Formed by heating camphoric acid or its salts (Bouillon-Lagrange, A. Ch. 23, 153; Laurent, A. Ch. 63, 207; Malaguti, A. Ch. 64, 151; Blumenau, A. 67, 119; Monoyer, J. Ph. [3] 45, 177). Formed also from camphoric acid by the action of (1 mol. of)  $\text{PCl}_5$  (Gerhardt, A. Chiozza, A. 87, 294), or conc.  $\text{H}_2\text{SO}_4$ , of  $\text{Ac}_2\text{O}$ , or of  $\text{AcCl}$  (Anschütz, B. 10, 1881). Long trimetric prisms (from alcohol) (Montgolfier, A. Ch. [5] 14, 5). V. sl. sol. water, v. sol. alcohol, v. e. sol. ether. Slowly converted by boiling water into camphoric acid. The statement of Brodie (Pr. 9, 361; 12, 655) that barium peroxide formed camphoric peroxide has been denied by Kingzett (C. J. 45, 93).

**Amide  $\text{C}_6\text{H}_{11}(\text{CONH}_2)_2$ .** Amorphous mass (Moitessier, A. 120, 253).

**Imide  $\text{C}_6\text{H}_{11}\text{C}_2\text{O}_2\text{NH}$ .** [180°] (in sealed tubes, Ballo, A. 197, 332). Formed by heating ammonium camphoramate at 160° (Laurent, Compt. chim. 1845, 147; A. 60, 327). Laminar. May be distilled.

**Ethylimide  $\text{C}_6\text{H}_{11}\text{C}_2\text{O}_2\text{NEt}$ .** [50°]. (275°). Colourless crystals. Prepared by dis-

tilling ethylamine camphorate (Wallach a. Kamenski, *B.* 14, 184; *A.* 214, 248).

**Allyl-imide**  $C_8H_{11}O_3 \cdot NO_2H$ . [49°]. Formed by heating camphoric acid with allyl thiocarbimide. Insol. water, sol. alcohol and ether.

**Phenyl-imide**  $C_8H_7O_3 \cdot NPh$ . [116°]. Formed, together with phenyl-camphoramidic acid, by warming camphoric anhydride with aniline (Gerhardt a. Laurent, *A.* 68, 35). Needles (from ether); insol. cold water.

**Di-ethyl-imido-imidine**  $C_{14}H_{21}N_2O$  i.e.

Liquid, v. cl. sol. water. Fps. salts of Cu and Fe. Prepared by the action of  $PCl_5$  on ethylamine-camphorate or by the action of ethyl-

amine on the chloride  $(C_8H_7 \begin{array}{c} \diagup CCl_2 \\ \diagdown CO \end{array} NEt)$  obtained

from  $PCl_5$  and camphoric-ethyl-imide. By  $HCl$  at  $200^\circ$  it is decomposed into ethylamine and camphoric-ethyl-imide. Salts.— $B'HCl$ : deliquescent crystals.— $B'III$ : sparingly soluble needles.— $(B'HCl)_2PtCl_6$ . Its *ethylo-iodide*  $B'EtI$ : [245°]; forms long colourless prisms (Wallach a. Kamenski, *B.* 14, 162; *A.* 214, 242).

**Nitrile**  $C_8H_7(CN)_2$ . Formed, in small quantity, together with hydrocarbons  $C_8H_{11}$  and  $C_{20}H_{32}$ , by distilling ammonium camphoramate with  $P_2O_5$  (Ballo, *A.* 197, 334). Crystalline; insol. water.

**Camphoramidic acid**  $C_8H_7(CONH_2)(CO_2H)$ . So-called '*amido-camphoric acid*'. The ammonium salt is formed by the action of  $NH_3$  on an alcoholic solution of camphoric anhydride (Laurent, *Compt. chim.* 1845, 147; *A.* 60, 326). Trimetric crystals; m. sol. hot water, v. sol. alcohol.— $NH_4A$  aq. [230°]. When heated with dry  $ZnCl_2$  it gives xylene tetrahydride and a terpene (Ballo, *B.* 12, 324).— $PbA_2$ .— $AgA$ .

**Phenyl-camphoramidic acid**  $C_8H_7(CONPhH)(CO_2H)$ . Formed by boiling the phenyl-imide of camphoric acid with alcoholic  $NH_3$ , or camphoric anhydride with aniline. Needles (from alcohol); v. sl. sol. boiling water.— $AgA$  (Laurent a. Gerhardt, *A.* 68, 36).

**Bromo-camphoric anhydride**

$C_8H_7Br \begin{array}{c} \diagup CO \\ \diagdown CO \end{array} O$ . From camphoric anhydride (10 g.) and  $Br$  (15 g.) at  $130^\circ$  (Woringer, *A.* 227, 3); an additive compound  $C_8H_7O_3Br$ , appears to be first formed (Wreden, *A.* 163, 330). Trimetric crystals (from chloroform).  $abc = 8866:1:5766$ .  $NH_3$  gives the imide of oxy-camphoric acid.

(a)-**Oxy-camphoric acid**  $C_{10}H_{15}O_5$ . Formed, together with pimelic acid, by fusing camphor with  $KOH$  (Hlasiwetz a. Grabowski, *A.* 145, 212). Thick liquid; the salts are amorphous.

(b)-**Oxy-camphoric acid**  $C_{10}H_{15}O_5$ . *Anhydride*  $C_{10}H_{11}O_4$  i.e.

$C_8H_7(CH_2)_2C_2O_2O$  (?) *Camphamic acid*. [201°]. Formed by boiling bromo-camphoric anhydride with water (Kachler, *A.* 162, 264). Monoclinic prisms (containing aq or 2aq) (Grünling, *A.* 227, 4). Sublimes at  $110^\circ$ . Decomposed on distillation giving  $CO_2$ , lauronic acid  $C_{11}H_{19}O_2$ , and 'campho-lactone'  $C_8H_{11}O_2$ . Water at  $180^\circ$

splits it up into  $CO_2$  and  $C_8H_{11}$  ( $119^\circ$ ).— $Ba(C_8H_7O_4)_2$  1 aq.— $Cd(C_8H_7O_4)_2$  3 aq.

**Ethyl ether**  $Et(C_8H_7O_4)_2$ . [63°]. From bromo-camphoric anhydride and alcohol at  $150^\circ$ . Prisms.

**Imide**  $C_8H_7NO_3$  i.e.  $C_8H_7(OH)(C_2O_2)NH$  (?) [208°]. *Amido-camphoric anhydride*. From bromo-camphoric anhydride and conc.  $NH_3$  aq at  $150^\circ$  (Wreden, *A.* 163, 339). Long needles (from alcohol). Sublimes at  $150^\circ$ . Converted by nitrous acid into the anhydride.

**Oxy-camphoramidic acid**  $C_8H_7NO_4$  i.e.  $C_8H_7(OH)(CONH_2)(CO_2H)$ . '*Amido-camphoric acid*'. [160°]. Formed by boiling the imide of oxy-camphoric acid with dilute  $KOH$  (Wreden, *A.* 163, 340). Prisms containing aq (from alcohol). On fusion it is converted into the parent imide. Converted into oxy-camphoric anhydride by  $HNO_3$ , by conc.  $HCl$  aq, or by  $H_2SO_4$ .— $CaA$ , 2 aq.

**Sulpho-camphoric acid** so-called.  $C_8H_7SO_4$ . [160°–165°]. *Sulphocamphylic acid*. Formed, together with  $CO_2$ , by heating camphoric acid or anhydride with conc.  $H_2SO_4$  (Walter, *A. Ch.* [3] 9, 177; Kachler, *A.* 169, 179). Triclinic prisms (containing 2aq);  $abc = 8515:1:7590$ ;  $\alpha = 82^\circ 39'$ ;  $\beta = 121^\circ 10'$ ;  $\gamma = 111^\circ 36'$  (Zepharovich, *Sitz. B.* 73, 7). V. e. sol. water, alcohol, and ether.  $HNO_3$  (S.G. 1.25) converts it into  $C_8H_7SO_3$ . Potash-fusion gives  $C_8H_{12}O_2$  [148°], insol. cold water, but separating from alcohol in monoclinic crystals.

Salts.— $(NH_4)_2A$  aq.— $KA$ .— $CaA$ .— $BaA$ .— $PbH_2A_2$  4aq; trimetric.— $PbA$ .— $BaCuA_2$ .— $AgA$ .

#### ISOMERIDES OF CAMPHORIC ACID.

**Levo-rotatory camphoric acid**  $C_{10}H_{15}O_4$ . [186°].  $[\alpha]_D = -46.3^\circ$  (in alcohol). Formed by the oxidation of levo-rotatory ( $[\alpha]_D = -38^\circ$ ) borneol to the corresponding camphor, by heating for several hours with a large excess of  $K_2Cr_2O_7$  (S.G. 1.27) (Chautard, *C. R.* 37, 166; Haller, *C. R.* 103, 64). Resembles camphoric acid in all respects except that its rotation though equal is opposite.

**Inactive camphoric acid**  $(C_{10}H_{15}O_4)_2$ . [204°]. S. 1; S. (alcohol) 33; S. (ether) 28 (C.). Formed by heating inactive camphor with  $HNO_3$  at  $100^\circ$ , or by mixing equal weights of dextro- and levo-camphoric acids (Chautard, *C. R.* 56, 698; Armstrong a. Tilden, *C. J.* 85, 757; Haller, *C. R.* 105, 66). Less soluble than its isomerides.

**Diethyl ether**  $Et_2A$ . (270°–275°). S.G. 1.503 (C.).

**Anhydride**  $(C_{10}H_{15}O_3)_2$ . [223°] (A. a. T.). S. (chloroform) 25; S. (ether) 4; S. (alcohol) 1.5 (C.). Formed by heating the acid.

An inactive camphoric acid [186°] was obtained by Muir (*C. J.* 37, 685) by oxidising the camphor of oil of sage.

**Meso-camphoric acid**  $C_{10}H_{15}O_4$ . [118°].

**Formation**.—1. Formed by heating dextro-camphoric acid (5 g.) with (20 c.c.) fuming  $HCl$  at  $140^\circ$  for 30 hours (Wreden, *Z.* [2] 7, 419; *A.* 163, 328; *B.* 6, 565).—2. By heating dextro-camphoric acid (5 g.) with  $HI$  (30 c.c. of S.G. 1.6) at  $160^\circ$ .—3. By heating camphoric acid with water at  $200^\circ$  (Jungfleisch, *B.* 6, 268, 680). 4. Together with 'sulphocamphoric acid' by the

action of  $H_2SO_4$  on camphor. Occurs also in small quantity in the preparation of camphoric acid from camphor and  $HNO_3$  (Kachler, A. 169, 179; 191, 146).

**Properties.**—Crystalline, but separates from alcohol and ether as an oil. More soluble than ordinary camphoric acid. Conc.  $H_2SO_4$  converts it on warming into 'sulphocamphoric acid.' When heated it gives the anhydride of ordinary camphoric acid. Boiling dilute HCl changes it into inactive camphoric acid.

**CAMPHORIDE**  $C_{10}H_{12}O_8$ . [222°]. Occurs together with galangin and alpinin in the galanga root (*Alpinia officinarum*). Flat yellow needles (containing aq), sublimable. Sol. hot alcohol, ether, and acetic acid, sl. sol. chloroform and benzene, insol. water. Dissolves in alkalis. On oxidation with dilute  $HNO_3$  it produces anisic and oxalic acids.

**Salts.**— $A''Pb$ : yellow amorphous pp.— $A''Pb_2O$ .— $A''Ba$  2aq: orange pp.

**Di-acetyl derivative**  $C_{10}H_{10}O_4(OAc)_2$ . [189°]. Colourless crystals. Insol. water. Sl. sol. alcohol.

**Di-benzoyl derivative**  $C_{10}H_{10}O_4(OBz)_2$ . [186°]. Fine white needles. Scarcely sol. alcohol, insol. water.

**Di-bromo-derivative**  $C_{10}H_{10}Br_2O_8$ . [225°]. Yellow needles. Sl. sol. alcohol (Jahns, B. 14, 2385).

#### CAMPHOR-IMIDO-ACETIC ETHER

$C_{14}H_{21}NO$ , i.e.  $C_8H_{11} \begin{smallmatrix} CO \\ CO \end{smallmatrix} N.CH_2.CO_2Et$ . [86°].

Formed by adding a solution of  $CH_2Cl.CO_2Et$  to a solution of sodio-camphorimide in absolute alcohol. Large transparent crystals (from alcohol), sol. ether (Haller a. Arth, C. R. 105, 281).

**CAMPHOR OIL.** An oil obtained, together with camphor, by distilling the wood of *Laurus camphora* with water. It contains chiefly of 'camphorogenol' but contains also several terpenes (q. v.).

**Camphorogenol**  $C_{10}H_{16}O_2$  or  $C_{10}H_{18}O_2$  or  $C_{10}H_{18}Oaq$  (?) S.G. 29.9794.  $[d]_D^{20} = 29.6^\circ$ . An oil, v. e. sol. alcohol and ether.  $HNO_3$  acts upon it forming a small quantity of camphor.  $CrO_3$  acts similarly. Excess of conc.  $HNO_3$  gives camphoric acid [185°],  $[a]_D^{20} = 40.3^\circ$ .  $Ac_2O$  has no action. Sodium reduces it, in alcoholic solution, to borneol, [198°], (212°),  $[a]_D^{20} = 22.9^\circ$ . With  $ZnCl_2$  it yields cymene (Yoshida, C. J. 47, 785; Oishi, C. N. 50, 275; Wallach, A. 227, 296; Lallemant, A. Ch. [3] 57, 404).

#### CAMPHOR-PHORONE v. PHORONE.

**CAMPHORONIC ACID**  $C_{10}H_{12}O_8$ . Mol. w. 218. [137°]. Formed by oxidising campholic or camphanic acids (Bredt, B. 18, 2989).

**Preparation.**—From camphor and  $HNO_3$ . Present in the mother liquor from which camphoric acid has separated. Obtained by means of the barium salt (Kachler) and purified by decomposing this with HCl, extracting with ether, boiling off the ether, dissolving in water, neutralising with lime and boiling. The pure calcium salt then separates (Bredt, A. 226, 261; cf. Kachler, B. 7, 1728; A. 159, 286; 162, 262; Kachler a. Spitzer, M. G. 173).

**Properties.**—Crystalline aggregates of needles, v. e. sol. water, alcohol, and wet ether, sl. sol. pure ether. Produces on distillation  $CO_2$ , iso-

butyric acid and the anhydride  $C_8H_{12}O_8$  [135°] which forms trimetric crystals,  $a:b:c = 96:1:82$ ; sol. water, alcohol and ether. This anhydride forms with  $NH_3$  the compound  $C_8H_{11}(NH_4)O_8$  [c. 128°], v. sol. water.

**Reactions.**—1.  $AcCl$  gives  $C_8H_{12}O_8$  and then the anhydride  $C_{10}H_{12}O_8$  [176°]; crystals, insol. cold alcohol and ether; reconverted into camphoric acid by boiling alkalis.—2. Br at 130° gives oxy-camphoric acid.—3. *Potash-fusion* gives isobutyric acid.—4. *Aqua-regia* forms two acids  $C_8H_{12}O_8$ .—5.  $KMnO_4$  gives  $HOAc$  and an acid  $C_8H_{11}O_4$  (Kachler, M. 5, 415).—6. The Ca salt distilled with lime gives a ketone  $C_8H_{10}O$ .

**Salts.**— $NH_4HA''$ : [128°].— $(NH_4)_2HA''$ : [148°].— $K_2HA''$  aq.— $C_8H_9A''$  12aq.— $BaHA''$  aq: m. sol. water.— $Ba_2A''$ : insol. water.— $Ba_3A''$  6aq.— $Ba_4A''$  10aq.— $ZnHA''$ : v. e. sol. water.— $CdHA''$  6aq.— $PbA''$  24aq.— $Cu_2A''$  2aq.— $Cu_4A''$  2aq.— $Ag_2A''$ :  $Ag_4A''$ :  $Ag_6A''$  aq.

**Mono-ethyl ether.**—The anhydride (302°) (or anhydrides liquid and solid [67°], Hjelt, B. 13, 797)  $C_{10}H_{11}EO_8$  of this ether is formed together with alcohol by distilling the di-ethyl ether.

**Di-ethyl ether**  $Et_2HA''$ . From the acid, alcohol, and HCl.

**Tri-ethyl ether**  $Et_3A''$ . (302°). From  $Ag_2A''$  and  $Et_3Cl$ . Liquid.

**Chloride**  $C_{10}H_{11}OCl$ . [131°]. Needles, sl. sol. water, sol. alcohol and ether.

**Mono-amie acid**  $C_8H_{11}(CONH_2)(CO_2H)_2$ .

**Anhydride**  $C_8H_{11}NO_8$ . [212°]. From liquid *mono-ethyl* camphoronate and alcoholic  $NH_3$  (Hjelt, B. 13, 798). By the same treatment the solid *ethyl* camphoronate gives a compound  $C_8H_{16}N_2O_4$  (2 di-amie acid) crystallising with  $HOEt$ . It melts at [145°] and is converted by boiling  $HClAq$  into camphoric acid.

**Di-amie acid**  $C_8H_{11}N_2O_4$ , i.e.  $C_8H_{11}(CONH_2)_2$ .  $[a]_D^{20} = 160^\circ$ . From di-ethyl camphoronate and  $NH_3$  at 120° (H.).  $HClAq$  converts it into a compound  $C_8H_{11}NO_8$  [212°].

**Constitution.**—Camphoric acid appears to contain 3 carboxyls:  $C_8H_{11}(CO_2H)_3$ , as shown by the salts and ethers.  $AcCl$  gives no acetyl derivative. The formation of an anhydride by distilling the ether does not prove it to be lactonic. Potash-fusion produces iso-butyric acid, hence it contains isopropyl. Since it does not split off  $CO_2$  on distillation, the carboxyls must be attached to different carbon atoms. Hence it is isopropyl-tricarballic acid,

**Oxy-camphoric acid**  $C_8H_{12}O_9$ . [c. 210°]. Formed by heating camphoric acid  $C_8H_{12}O_8$  (1 mol.) with Br (1 mol.) for two hours at 130° (Kachler, A. 159, 296). Monoclinic crystals (containing a p.),  $a:b:c = 1.4918:1:0.9808$ ;  $\beta = 86^\circ 50'$ . According to Zepharovich (J. 1877, 641) they are dimorphous. V. sol. water, alcohol, and ether; may be distilled.

**Salts.**— $KHA''$  aq. crystals.— $K_2A''$ : gummy.— $BaA''$  aq: nearly plates.— $Pb_2(C_8H_9O_8)_2$  2aq.— $Ag_2A''$ .

#### Hydro-oxy-camphoric acid v. CAMPHOR.

**CAMPHOROXIM**  $C_{10}H_{11}NO$  i.e.  $C_{10}H_{16}N.OH$ . [115°]. (c. 250°). Formed by the action of hydroxylamine on camphor (Nägeli, B. 16, 498).

**Long needles.** Smells like camphor and rotates on water. Sol. alcohol, ether, acids and alkalis.

**Reactions.**—1. Hydroxylamine is not split off by heating with aqueous HCl even at 120°.—2. By heating with acetyl chloride it loses H<sub>2</sub>O yielding the nitrile of campholenic acid C<sub>10</sub>H<sub>13</sub>N (Goldschmidt a. Zürrer, B. 17, 2069).—3. Is reduced in alcoholic solution by metallic sodium

to bornylamine C<sub>10</sub>H<sub>17</sub>N,  $\begin{array}{c} \text{CH}_2 \\ | \\ \text{C}_6\text{H}_9\text{NH}_2 \end{array}$ . The oxim-anhydride is reduced to the isomeric camphylamine (Leuchart a. Bach, B. 20, 111).

**Hydrochloride** C<sub>10</sub>H<sub>13</sub>NOH.HCl: white powder, sl. sol. water, v. sol. alcohol and acids.

**Sodium salt.**—C<sub>10</sub>H<sub>13</sub>N(O<sup>-</sup>Na): white powder, v. sol. water and hot alcohol.

**Ethylether** C<sub>10</sub>H<sub>13</sub>N(OEt): (209°); mobile liquid.

**Anhydride** C<sub>10</sub>H<sub>13</sub>N: (217°), liquid; formed by heating camphoroxim with acetyl chloride. Is the nitrile of CAMPHOLENIC ACID (q. v.) (Nägeli, B. 16, 2981).

**Isocamphor-oxim** is the amide of CAMPHOLENIC ACID (q. v.).

**CAMPHO-TERPENE** v. TERPENES.

**CAMPHERE** v. PHORONE.

**CAMPHERIC ACID** or **CAMPHERETIC ACID** so called by Schwanert (A. 128, 77) has been shown by Kaehler (A. 191, 143) to be a mixture of camphoric and camphoronic acids.

**CAMPHYLAMINE** C<sub>10</sub>H<sub>19</sub>N possibly C<sub>10</sub>H<sub>13</sub>(CH<sub>2</sub>NH<sub>2</sub>):CH<sub>2</sub> (195°). Prepared by adding metallic sodium to an alcoholic solution of campholenic nitrile (camphor-oxim-anhydride). Colourless liquid. Volatile with steam. Readily absorbs CO<sub>2</sub> from the air and solidifies to a crystalline carbonate. Primary base.

**Salts.**—B<sub>2</sub>H<sub>2</sub>Cl<sub>2</sub>.PtCl<sub>4</sub>: glistening golden plates, nearly insol. water.—B<sub>2</sub>H<sub>2</sub>Cl<sub>2</sub>HgCl<sub>2</sub>: colourless orthorhombic plates; sol. hot water.—B<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>.aq: [194°], colourless orthorhombic glistening crystals, v. sc. hot water.—B<sub>2</sub>H<sub>2</sub>SO<sub>4</sub>.aq: long rhombic prisms, m sol. cold water.—B<sub>2</sub>H<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>: orange-red plates.—The **picrate** forms fine yellow needles, [199°–194°].

**Benzoyl derivative** C<sub>10</sub>H<sub>13</sub>NBz: [77°], colourless prisms (Goldschmidt a. Schulhof, B. 18, 3297; 19, 708; 20, 483).

**Isomeride** v. BORNYLAMINE.

**CAMPHYL-PHENYL-THIO-UREA**

SC(NHC<sub>6</sub>H<sub>5</sub>)(NHC<sub>10</sub>H<sub>17</sub>). [118°]. Formed by combination of phenyl-thiocarbimide and camphylamine. Short colourless prisms. V. sol. alcohol and benzene, sl. sol. ether; v. sol. ligroin (Goldschmidt a. Schulhof, B. 19, 712).

**CAMPHYL-DI-THIO-CARBAMIC ACID** C<sub>10</sub>H<sub>17</sub>.NH<sub>2</sub>.CS<sub>2</sub>.SH. The camphylamine salt, C<sub>10</sub>H<sub>17</sub>.NH<sub>2</sub>.CS<sub>2</sub>.SH<sub>2</sub>(C<sub>10</sub>H<sub>17</sub>), is formed by mixing camphylamine with CS<sub>2</sub>. White powder, [110°–116°], sol. benzene. The sodium salt C<sub>10</sub>H<sub>17</sub>.NH<sub>2</sub>.CS<sub>2</sub>.SNa forms white glistening plates, sol. cold, decomposed by hot, water (Goldschmidt, B. 19, \*12).

**CANADA BALSAM.** Exudes from incisions in the bark of *Abies balsamea*. Transparent thick liquid with refractive index (1.532) nearly the same as that of crown glass. Dextro-rotatory. Steam-distillation separates a laevo-rotatory terpene (167°), which forms a crystalline compound with HCl (Donastre, J. Ph.

8, 572; Caillot, J. Ph. 16, 436; Wirsen, *Dissertation*, Helsingfors, 1849).

**CANADOL.** A term applied by Vohl (D. P. J. 172, 319) to that portion of the volatile hydrocarbons of Canadian and Pennsylvanian petroleum which boils at 60° and has a S.G. .65 to .70. It is also called petroleum-ether or ligroin. It consists chiefly of *n*-hexane.

**CANANGA OIL.** *Alan-gilan*. From *Cananga odorata*. Neutral oil (170°–290°). It contains benzoyl and acetyl derivatives, a compound that unites with NaHSO<sub>3</sub>, and probably a phenol (Flückiger, Ph. [3] 11, 934).

**CANARIUM.** The fixed oil of *Canarium commune* contains 51 p.c. olein and 49 p.c. stearin and myristin (Oudemans, J. pr. 99, 407).

**CANAUBA WAX** v. CANAUBA w.x.

**CANE SUGAR** v. SUGAR.

**CANNABIS INDICA.** Indian hemp when distilled with steam yields an essential oil C<sub>15</sub>H<sub>21</sub> (257°); V.D. 7.1; S.G. .93; [α]<sub>D</sub> = –10.81 at 25.5° (in chloroform). The oil resinifies on exposure (Valenta, G. 10, 479; 11, 196; cf. Martius, C. C. 1856, 225; Personne, J. Ph. [3] 31, 46). HNO<sub>3</sub> (S.G. 1.32 to 1.42) acting on the resinous extract of Indian hemp forms 'oxycannabene' C<sub>20</sub>H<sub>28</sub>N<sub>2</sub>O (Bolas a. Francis, C. J. 22, 417; C. N. 24, 77). This separates from methylated spirit in flat yellow prisms [176°], insol. water, sl. sol. alcohol. Indian hemp, and its alcoholic extract, contain a poisonous resin (T. a. H. Smith, Ph. 6, 127, 171; Martius). Hay (Ph. [8] 13, 998) has extracted a crystalline alkaloid 'tetano-cannabine' which produces tetanus in frogs. The fixed oil from hemp-seed (*Cannabis sativa*) is probably a fatty oil, though Lefort (C. R. 35, 734) gives it the formula C<sub>11</sub>H<sub>22</sub>O<sub>2</sub> and describes C<sub>11</sub>H<sub>22</sub>Cl<sub>2</sub>O<sub>2</sub> and C<sub>11</sub>H<sub>20</sub>Br<sub>2</sub>O<sub>2</sub> as products of substitution.

**CANNON-METAL** v. COPPER, ALLOYS OF.

**CANTHARENE** C<sub>14</sub>H<sub>12</sub>, i.e. C<sub>8</sub>H<sub>4</sub>(CH<sub>3</sub>)<sub>2</sub> [1.2]. (134°). *o*-Xylene-di-hydrate.

**Formation.**—1. By heating cantharic acid with fused KOH.—2. By heating cantharic acid or cantharidin with water at 300°, CO<sub>2</sub> being split off.—3. In a pure state by boiling with conc. aqueous KOH, the product C<sub>10</sub>H<sub>12</sub>O<sub>2</sub>l<sub>2</sub> obtained together with cantharic acid by the action of HI upon cantharidine (Piccard, B. 12, 577; 19, 1404).

**Properties.**—Liquid, smelling like turpentine and camphor. Absorbs oxygen with avidity. Dilute HNC<sub>2</sub> oxidises it to *o*-toluic and phthalic acids.

**CANTHARIC ACID** C<sub>10</sub>H<sub>12</sub>O<sub>4</sub>, i.e. (C<sub>8</sub>H<sub>4</sub>Q)CO.CO<sub>2</sub>H. [278° cor.]. S. 85 at 15°; 8.5 at 130°. Prepared by heating 1 pt. of cantharidine with 4 pts. of HI (1.96 S.G.) for 2½ hours at 100°. Trimetric crystals (from water); v. e. sol. alcohol, v. sl. sol. ether. Distilled with lime it gives cantharene, a little xylene, butyric acid, and di-methyl-benzoic acid. It is an α-ketonic acid, for on heating with di-methylaniline and ZnCl<sub>2</sub> it evolves CO<sub>2</sub> and yields a condensation product C<sub>24</sub>H<sub>22</sub>ON<sub>2</sub>; the latter is converted into a green colouring-matter by MnO<sub>2</sub> into a violet colouring-matter by chloranil or arsenic acid.—A'Ag: white pp.—KA': slender needles.—PbA'z.aq.

**Methyl ether** A'Me: (210°–220°) at 50 mm.; colourless liquid.

*Ethyl ether* A. Et (c. 800°).

*Oxim*  $C_{10}H_{11}O_2(NH)$ : [175°-180°]; colourless four-sided plates (Piccard, B. 10, 1504; 11, 2121; Homolka, B. 19, 1086).

**CANTHARIDIC ACID**  $C_{10}H_8O_4$ , i.e.  $(C_6H_4O_2)CO.CO_2H$ . The alkaline salts are formed by heating cantharidin with aqueous alkalis. When a cold solution of the salts is treated with acids, the free cantharidic acid appears to be formed, but on warming the solution it loses  $H_2O$  and cantharidin is precipitated. With hydroxylamine it gives an *oxim*, from the salts of which acids liberate the *oxim* of cantharidine.—Ag. A' aq.—Ag. A'' 2aq. (NH<sub>4</sub>)' A' aq.—H. A' aq.—Cd A' aq.—K<sub>2</sub>CrO<sub>4</sub> 2aq. *Di-methyl ether* A. Me: [91°]; large flat glistening prisms; sol. alcohol, ether, and hot water, sl. sol. cold water (Homolka, B. 19, 1082; Dragendorff a. Masing, Z. 1867, 464; Masing, J. 1872, 841).

**CANTHARIDIN**  $C_{10}H_8O_4$ . Lactone of cantharidic acid. [218° gor.]. S. 02 at 15°; 29 at 100°; S. (alcohol) 2.1 at 78°; 13 at 15°; S. (benzene) 3.88 at 80°; .51 at 15° (Rennard); S. (ether) .11 at 18°; S. (CS<sub>2</sub>) .06 at 18°; S. (CHCl<sub>3</sub>) 1.2 at 18° (Blum).

*Occurrence*.—In Spanish flies (*Lytta vesicatoria*) and many other insects (Thierry, A. 15, 815; J. Ph. 21, 44; Robiquet, A. Ch. 76, 302; Gössmann, A. 86, 317; Pocklington, Ph. [3] 3, 681; Regnault, A. Ch. [2] 68, 159; Warner, Am. J. Ph. 28, 193; Ferrer, J. 1860, 597; Mortreux, J. Ph. [3] 46, 33; Fumouze, J. Ph. [4] 6, 161; Blum, Z. [2] 2, 675; Dragendorff, Z. [2] 3, 187, 464; 4, 308; Rennard, C. C. 1872, 568; Wolff, Ar. Ph. [3] 10, 22; Piccard, B. 10, 1504).

*Preparation*.—1. Powdered cantharides are extracted with chloroform or ether, the solvent is evaporated and the residue freed from fat by washing with CS<sub>2</sub>.—2. Cantharides are mixed with water and MgO, dried, treated with dilute  $H_2SO_4$  and then shaken with ether.

*Properties*.—Trimetric plates. Blisters the skin. Sublimes readily at 85° (Blyth).

*Reactions*.—1. HI forms cantharic acid.—2. By distillation with P<sub>2</sub>S<sub>5</sub> it gives *o*-xylene (Piccard, B. 12, 580).—3. By heating with alkalis it is converted into salts of cantharidic acid  $C_{10}H_7O_4$ , from whose hot solutions cantharidin is re-precipitated on the addition of acids.

*Oxim*  $C_{10}H_{11}O_2(NH)$ : [166°]; splendid long glistening prisms; v. e. sol. alcohol and ether, v. sol. hot water, sl. sol. cold. By conc. HCl at 150° it is split up into its constituents.— $C_{10}H_{12}O_4(NOAg)$ : four-sided prisms.— $C_{10}H_{12}O_4(NOMe)$ : [134°]; large colourless prisms; v. e. sol. alcohol and ether, v. sol. hot, sl. sol. cold, water (Homolka, B. 19, 1082).

**Compound**  $C_{10}H_7O_4I$ . 'Cantharidin iodide' is formed as a by-product (5-8 p.c.) in the preparation of cantharic acid by the action of HI (1.96 S.G.) upon cantharidin at 85°. Crystalline solid. V. sol. benzene and chloroform, sl. sol. alcohol, insol. water. On boiling with conc. KOH it is converted into pure cantharone (*o*-xylene-di-hydride)  $C_8H_8(CH_3)_2$  (Piccard, B. 19, 1404).

**CAOUTCHOUC**. *India rubber*. This substance is obtained from the milky sap of

various trees belonging to several natural orders. The sap, which is obtained by making an incision in the bark of the tree, is a white creamy liquid with a sp. gr. 1.012.

The caoutchouc exists in the sap in the form of minute globules, and is consolidated in various ways, even by heating over a smoky fire which produces the brown colour of the commercial article.

Caoutchouc is colourless when pure, it is a bad conductor of heat and a non-conductor of electricity. S.G. about .925. At ordinary temperatures it is soft, flexible, and very elastic, but at about 10° it begins to lose its elasticity, and at 0° becomes hard and rigid. When heated it loses its elasticity and becomes soft, slowly resuming its original properties when cooled; if heated to 150°-200° it melts, and after this it remains semi-liquid and sticky on cooling. It burns readily with a smoky flame, leaving little or no ash.

Exposure to air in the absence of light produces little effect on caoutchouc, but light and air together cause it to lose its elasticity and become glutinous, due to the absorption of oxygen (Spiller, C. J. 18, 44; Miller, *ibid.* p. 273).

Caoutchouc is insoluble in water, but when immersed in it becomes white and increases in bulk, absorbing about 25 p.c. of its weight of water, which is given up again on exposure to air. Alcohol acts upon it in a similar way.

Dilute acids do not affect it, but it is attacked by strong nitric or sulphuric acid. Chlorine renders it hard and brittle. Alkalis produce little effect.

Ether, benzene, mineral oil, sulphide of carbon, chloroform, oil of turpentine, oil of caoutchouc, and many essential and fixed oils, act upon caoutchouc, causing it to swell greatly and become gelatinous and soft. The action of these solvents appears to be to dissolve one constituent part of the caoutchouc, leaving the less soluble part in a disintegrated condition.

According to Payen, sulphide of carbon with about 5 p.c. of absolute alcohol is the best solvent.

Caoutchouc is composed of carbon and hydrogen. The proportions vary in different analyses C. 86.1-90.6 p.c.; H. 10-12.8 p.c. It appears to consist chiefly of two hydrocarbons, which can be partly separated by the prolonged action of a solvent, but the proportion of these constituents obtained varies according to the solvent employed. The more soluble part is soft and ductile, while the less soluble is tenacious and elastic.

When caoutchouc is subjected to dry distillation an oil consisting of a mixture of various hydrocarbons is obtained. This is called oil of caoutchouc.

Among the constituents of this oil are isoprene  $C_5H_8$  (37°-38° S.G. .882; caoutchene  $C_{10}H_{16}$  (171°) S.G. .842; and heveone (315°) S.G. .921 (Himly, A. Ch. 27, 41; Gregory, *ibid.* 16, 61; G. Williams, Pr. 10, 517; Bouchardat, J. Ph. 1837, 454; Bl. 24, 108; C. R. 89, 861).

When isoprene is acted on by strong hydric chloride a mixture of the mono- and di-hydrochlorides, together with a solid substance, is obtained. This latter is identical in its proper-

ties with caoutchouc (Bouchardat, *C. R.* 89, 1117).

**Vulcanised caoutchouc.**—When caoutchouc is heated to about 115° in contact with sulphur, it absorbs some of the latter and becomes vulcanised. The introduction of the sulphur can be attained in many ways, immersion in a mixture of carbon disulphide and chloride of sulphur, or in a solution of polysulphide of calcium, &c.

About 2 p.c. of sulphur appears to enter into combination with the caoutchouc. If more than this quantity is introduced the excess remains mixed with the rubber and can be dissolved out by the ordinary solvents of sulphur, while the combined sulphur cannot be so extracted. An excess of sulphur renders the caoutchouc less durable. Vulcanised caoutchouc does not lose its elasticity at a low temperature and does not soften so easily with heat as ordinary rubber. It is less affected by solvents than pure caoutchouc.

The ordinary vulcanised rubber, besides containing an excess of sulphur, is often adulterated with 40-60 p.c. of mineral matter.

**Ebonite.**—When caoutchouc is heated with half its weight of sulphur, with or without the addition of some mineral matter, a hard dark substance which can be polished is obtained. This is much used for insulating purposes, but according to Wright (*Am. S.* [3] 4, 29) it becomes hygroscopic when exposed to the action of ozone owing to the formation of  $H_2SO_4$ . Ebonite is little affected by the solvents of caoutchouc.

C. J. W.

#### CAPILLARITY v. PHYSICAL METHODS, Sect.

##### MISCELLANEOUS.

**CAPRAMIDE** the *Amide* of DECAIC ACID (*q. v.*). The name has also been applied to the *amides* of OCTOIC ACID (*q. v.*) and UNDECIC ACID (*q. v.*).

**CAPRAMIDOXIM** v. HEXAMIDOXIM.

**CAPRIC ACID** v. DECAIC ACID.

**CAPRIC ALDEHYDE** v. DECAIC ALDEHYDE.

**CAPRILAMIDE** v. *Amide* of OCTOIC ACID.

**CAPRILIC ACID** v. OCTOIC ACID.

**CAPRILONE** v. DI-HEPTYL-KETONE.

**CAPRILONITRILE** v. *Nitrile* of OCTOIC ACID.

**CAPRINONE** v. DI-ENNYL-KETONE.

**CAPRO-AMIDE** v. *Amide* of HEXOIC ACID.

**CAPRO-ANILIDE** v. *Anilide* of HEXOIC ACID.

**CAPROIC ACID** v. HEXOIC ACID.

**CAPROIC ALDEHYDE** v. HEXOIC ALDEHYDE.

**CAPRO-LACTONE** v. *Lactone* of OXY-HEXOIC ACID.

**CAPRONE** v. DI-AMYL-KETONE.

**CAPRONITRILE** v. *Nitrile* of HEXOIC ACID.

**CAPROYL** = HEXOYL.

**CAPROYL AMIDE** v. *Amide* of HEXOIC ACID.

**CAPROYL CHLORIDE** v. *Chloride* of HEXOIC ACID.

**CAPRYL ALCOHOL** v. OCTYL ALCOHOL.

**CAPRYL-AMIDE** v. *Amide* of OCTOIC ACID.

**CAPRYLAMINE** v. OCTYLAMINE.

**CAPRYL CHLORIDE** v. *Chloride* of OCTOIC ACID; also OCTYL CHLORIDE.

**CAPRYL-BENZENE** v. OCTYL-BENZENE.

**CAPRYLENE** v. OCTYLENE.

**CAPRYLENE HYDRATE** v. OCTYL ALCOHOL.

**CAPRYLIC ACID** v. OCTOIC ACID.

**CAPRYLIC ALCOHOL** v. OCTYL ALCOHOL.

**CAPRYLIC ALDEHYDE** v. OCTOIC ALDEHYDE.

#### CAPRYLIDENE v. OCTINENE.

**Caprylidene tetrabromide** v. **TETRA-BROMO-OCTANE.**

**CAPRYLONE** v. DI-HEPTYL-KETONE.

**CAPRYLONITRILE** v. *Nitrile* of OCTOIC ACID.

**CAPRYL-PHENYL-AMINE** v. *p*-AMIDOPHENYL OCTANE, p. 178.

**CAPSAICIN**  $C_8H_{17}O_3$ , [59°].

**Preparation.**—Powdered cayenne pepper (*Capsicum fastigiatum*) is extracted with ether, the extract is evaporated, dissolved in hot alcoholic KOH, diluted with water, p.p.d. by  $BaCl_2$ , and the dried pp. treated with ether. On evaporating the extract, an oily red liquid remains, which is dissolved in dilute potash, and p.p.d. by addition of ammonium chloride.

**Properties.**—Colourless prismatic crystals, insol. water, sol. alcohol. Begins to volatilise at 100°. Powerful irritant. The pungent taste is removed by heating with potassium bichromate and dilute sulphuric acid.  $BaCl_2$  and  $CaCl_2$  in alcoholic solution give a pp. sol. ether;  $AgNO_3$  a pp. sol. ammoniac;  $FeCl_3$  a red pp. when warmed (Thresh, *Ph.* [3] 7, 21, 259, 473).

**CAPSICINE.** An alkaloid which may be extracted by benzene from the fruit of *Capsicum fastigiatum*. The benzene is evaporated, and the residue dissolved in ether, from which the alkaloid is obtained by shaking with dilute  $H_2SO_4$  (Thresh, *Ph.* [3] 6, 941). Needles; insol. water, v. sol. alcohol and ether; may be sublimed. Volatile with steam. It is not pungent. The hydrochloride crystallises in cubes and tetrahedra, the sulphate in prisms.

**CAPSULÆSCIC ACID**  $C_{13}H_{21}O_8$ . An acid obtained from the husks of the horse-chestnut (Rochleder, *Z.* 1867, 83). Crystals; may be sublimed.  $FeCl_3$  turns its solution greenish-blue.

**CARAGHEEN MOSS.** *Irish pearl moss.* A gelatinous seaweed (*Chondrus crispus*). Swells up in cold water, almost entirely dissolves in hot water. P.p.d. by  $Pb(OAc)_2$ . Appears to be chiefly composed of a carbohydrate, which is insol. Schweizer's solution, and not turned blue by  $H_2SO_4$  and I (Schmidt, *A.* 51, 56; Flückiger u. Obermayer, *N. R. P.* 1868, 350). Caragheen moss gives galactose when boiled with dilute  $H_2SO_4$  (Haediecke, Bauer, a. Tollens, *A.* 238, 302).

**CARAJURA.** A red dye, probably identical with chieca red. Insol. water, sol. alcohol and dilute alkalis, reppd. by acids (Virey, *J. Ph.* 1844, 151).

**CARAMEL.** A black substance obtained by heating cane-sugar at c. 200°. It is said to be a mixture of caramelan  $C_{12}H_{20}O_5$ , caramelen  $C_{36}H_{56}O_{15}$ , and caramelin  $C_{36}H_{102}O_{51}$ . They all reduce Fehling's solution. Dilute (84 p.c.) alcohol extracts caramelan, cold water then dissolves caramelen, leaving caramelin. Caramelin is a colourless, brittle, deliquescent resin.— $C_{12}BaH_{10}O_5BaO$ .— $C_{12}PbH_{10}O_5$ .— $C_{12}PbH_{10}O_5PbO$ . Caramelen is a mahogany-coloured solid.— $C_{36}H_{56}BaO_{15}$ .— $C_{36}H_{56}PbO_{15}$ . Caramelin is a glittering black solid, sol. boiling water.— $C_{36}H_{102}BaO_{51}$ .— $C_{36}H_{102}BaO_{51}BaO$ .— $C_{36}H_{102}PbO_{51}$  (Gélis, *A. Ch.* [3] 52, 352). Caramelan and caramelen are crystalloids, caramelin is a colloid. The formulae and purity of these bodies are, of course, very doubtful; other

observers have arrived at somewhat different results, indeed the nature of the resulting products depends upon the temperature used in preparing them (Péligot, *A. Ch.* [2] 67, 172; Vöckel, *A.* 85, 59; Maumene, *C. R.* 39, 422; Graham, *C. J.* 15, 258; Thomson a. Sherlock, *C. N.* 25, 242, 282).

**CARAWAY OIL.** Oil of caraway contains a terpene (*q. v.*)  $C_{10}H_{16}$ , identical with citrene, and carvol (*q. v.*)  $C_{10}H_{14}O$ .

**CARB-ACETO-ACETIC ETHER** is *mesitene-lactone carboxylic acid*, p. 20.

**CARBACETOXYLIC ACID**  $C_5H_7O_4$ . A syrupy acid, said to be formed by the action of moist  $Ag_2O$  on  $\beta$ -chloro-propionic acid and on  $\alpha$ -di-chloro-propionic ether. Reduced by sodium-amalgam to glyceric acid, and by  $H_2$  to pyruvic acid (Wichelhaus, *A.* 143, 7; 144, 351; Klimenko, *B.* 3, 468; 5, 477; 7, 1406; cf. Beekurts a. Otto, *B.* 10, 2039).

**TRI-CARBALLYLIC ACID**  $C_6H_8O_6$  i.e.  $CO_2H.CH(CH_2.CO_2H)_2$ , *s*-Propane tri-carboxylic acid. Mol. w. 176. [158°]. S. 40.5 at 14°.

**Formation.**—1. In the preparation of sugar from beet-root (Lippmann, *B.* 11, 707; 12, 1649; Weyer, *C. J.* 38, 864).—2. By the saponification of its nitrile which is prepared by the action of  $KCy$  on *s*-tri-bromo-propane in alcohol (M. Simpson, *Pr.* 12, 236; 14, 77; *C. J.* 18, 331).—3. By reducing aconitic acid or its ether with sodium-amalgam (Dessaignes, *C. R.* 55, 510; Wichelhaus, *A.* 132, 61; Hlasiwetz, *Z.* 1864, 734).—4. By the action of potash on the product of the action of  $KCy$  on  $\beta$ -chloro-isocrotonic ether (obtained from aceto-acetic ether and  $PCl_5$ ) (Claus a. Lischke, *B.* 14, 1089).—5. In the same way from  $\alpha$ -chloro-crotonic ether or from di-chloro-propylene (pictelohydrin) (Claus, *B.* 5, 358; 9, 223; *A.* 170, 131; 191, 63).—6. Appears to be formed by the action of  $HCl$  and  $KClO_3$  on gallic acid (Frieder, *A.* 177, 292).—7. Acetyl-succinic ether is converted by  $Na$  into acetyl-tri-carballylic ether  $CH_3.CO.C(CH_2.CO_2Et)_3$ ,  $CO_2Et$  whence alcoholic  $KOH$  or baryta-water produce tri-carballylic acid (Miehle, *A.* 190, 322).—8. By the oxidation of di-allyl-acetic acid by dilute  $HNO_3$  (Wolff, *A.* 201, 53).—9. By boiling citraconic acid with zinc and  $HCl$  (Behrmann a. Hofmann, *B.* 17, 2692).—10. From propane tetra-carboxylic acid  $(CO_2H.CH_2)_2(CO_2H)_2$  by heat (Bischoff, *A.* 214, 66).

**Properties.**—Hard short trimetric prisms (from water); v. sol. water and alcohol, sl. sol. ether. The ammonium salt gives with  $BaCl_2$  or  $CaCl_2$  no pp., even on adding  $NH_3$ .  $b(OAc)_2$  gives a white pp.  $Fe_2Cl_6$  gives a red pp.

**Salts.**— $Na_2HA'''2aq?$  —  $KH_2A'''$ . —  $Ca_2A'''4aq$ . —  $BaHA'''$ . —  $Ba_2A'''6aq$ . —  $Pb_2A'''4$ . —  $Cu_2A'''4$ . —  $Ag_2A'''4$ .

**Tri-ethyl ether**  $Et.A'''4$  (c. 300°).

**Tri-isoamylether**  $(C_4H_9)_3A'''$  (above 360°).

**CARBAMIC ACID**  $CH_3.NH_2$  i.e.  $NH_2.CO_2H$ . *Amido-formic acid*. *Amide of carbonic acid*. Not known in the free state. The ammonium salt is formed by the union of dry or moist  $CO_2$  (1 vol.) with gaseous  $NH_3$  (2 vols.) (J. Davy, *N. Ed. P. J.* 16, 345; Rose, *P.* 46, 352; *N.* 30, 47). Formed also by sublimation of neutral ammonium carbonate, and therefore occurs in commercial ammonium carbonate. Formed also

by oxidising glycocoll, leucine, tyrosine, and albumen, with alkaline  $KMnO_4$  (Drechsel, *J. pr.* [2] 12, 417; cf. Hofmeister, *J. pr.* [2] 14, 173). It may be conveniently prepared by digesting commercial ammonium carbonate with saturated aqueous  $NH_3$  for 30 or 40 hours at 20°–25° (Divers, *C. J.* 23, 215; cf. Kolbe a. Basaroff, *C. J.* 1, 194).

**Reactions.**—1. *Acids decompose carbonates* with formation of  $CO_2$  and  $NH_3$ .—2. *Boiling water* converts carbonates into carbonates.—3. *Strongly heating* converts the  $Na$  salt into sodium cyanate and  $H_2O$  (Drechsel, *J. pr.* [2] 16, 199).

**Salts.**—The carbonates are soluble in water (difference from most carbonates).— $NH_4A'$  (*v. supra*). Deliquescent plates. Its aqueous solution quickly changes to carbonate, but it is stable in presence of excess of  $NH_3$  in the cold. At 60° it is completely split up into  $CO_2$  and  $NH_3$  (Naumann, *A.* 160, 1; *B.* 18, 1157; Horstmann, *A.* 187, 48; Prekmann, *B.* 18, 1154). In a sealed tube at 140° it forms urea.— $NaA'$  aq: formed by adding  $NaOH$  to an alcoholic solution of the ammonium salt; prisms.— $KA'$ : deliquescent.— $CaA'_2$  aq: ppd. by adding lime and alcohol to a solution of  $NH_4A'$  at 0°; crystalline powder, sol. water, the solution quickly deposits  $CaCO_3$ . When strongly heated it leaves calcium cyanamide.— $SA'_2$ .— $BA'_2$ .

**Chloride**  $OC(NH_2)Cl$ . [c. 50°]. (62°). Prepared by passing a stream of dry  $COCl_2$  into  $NH_4Cl$  heated to about 400°. Long broad needles. Strong odour. On keeping it slowly changes into cyanamide with evolution of  $HCl$ . By water it is decomposed into  $NH_4Cl$  and  $CO_2$ . On vaporisation it probably dissociates into cyanic acid and  $HCl$ , which again recombine on cooling. By  $CaO$  it is converted into cyanic acid. With aromatic hydrocarbons in presence of  $Al_2Cl_3$  i.e. gives amides of aromatic acids (Gattermann a. Schmitt, *B.* 20, 858).

**Carbamic ethers.** *Synthesis.*

**Preparation.**—1. From chloro-formic ethers and  $NH_3$ .—2. From cyanic acid and alcohols.—3. From cyanogen chloride and alcohols.—4. By heating alcohols with urea nitrate.

**Properties.**—Solid substances, sl. sol. water, v. sol. alcohol and ether; may be distilled.

**Reactions.**—1. Heating with  $NH_3$  gives urea. 2.  $P_2O_5$  gives cyanates. 3. Alcoholic  $KOH$  acts upon carbamic ethers of the fatty series according to the equation:  $NH_2.CO_2C_nH_{2n+1} + KOH = KN.CO_2 + C_nH_{2n+1}OH + H_2O$  (Arth, *Bl.* [2] 45, 702; *A. Ch.* [6] 8, 428). Bornyl and menthyl carbonates act similarly.

**Methyl ether**  $MeA'$ . [52°]. (177°). S. 217 at 110°; S. (alcohol) 73 at 15° (Echevarria, *A.* 79, 110).

**Ethyl ether**  $EtA'$ . *Urethane*. Mol. w. 89. [c. 50°]. (c. 182°). Formed by the above methods (Dumas, *A. Ch.* [2] 54, 233; *A.* 10, 284; Liebig a. Wöhler, *A.* 54, 370; 58, 260; Wurtz, *A.* 79, 286; *C. R.* 22, 503; Bunte, *Z.* [2] 6, 96; *A.* 151, 181). Also from carbonic ether and  $NH_3$  (Cahours, *C. R.* 21, 629; *A.* 56, 266).

**Reactions.**—Alcoholic potash, at the ordinary temperature, gives large crystals of potassium cyanate. In this case  $NH_4.CO_2K$  is not formed as an intermediate product. A solution of

urethane in absolute ether, treated with K or Na gives the derivatives  $\text{KNH.CO.Et.}$  and  $\text{NaNH.CO.Et.}$  Of these, the Na derivative is sufficiently stable for analysis. It is v. sol. absolute alcohol, insol. absolute ether. With alcoholic potash containing water  $\text{K}_2\text{O}$ , is obtained. The body  $\text{HgN.CO.OEt}$  is obtained by mixing alcoholic solutions of urethane,  $\text{HgCl}_2$ , and  $\text{KHO}$  (Mulder, *R. T. C.* 3, 170).

Acetyl derivative  $\text{NHAc.CO.Et.}$  [78°] (Conrad a. Salomon, *J. pr.* [2] 10, 23).

Chloro-ethyl ether  $\text{H.N.CO.C}_2\text{H}_5\text{Cl}$ . [76°]. From  $\text{NH}_3$  and the chloro-ethyl ether of chloroformic acid. Prisms. V. sol. water, alcohol and ether (Nemirowski, *J. pr.* [2] 31, 174).

n-Propylether  $\text{PrA'}$ . [53°]. (195°) (Cahours, *J.* 1873, 748; Roemer, *B.* 6, 1102). Long prisms.

Isobutyl ether  $\text{C}_4\text{H}_9\text{A'}$ . [55°]. (207°) (Mylus, *B.* 5, 973; Humann, *A. Ch.* [3] 44, 840; *A.* 95, 372).

Isoamyl ether  $\text{C}_5\text{H}_{11}\text{A'}$ . [60°]. (220°) (Medlock, *A.* 71, 106; Wurtz, *J. Ph.* [3] 20, 22). Needles.

Octylether  $\text{C}_8\text{H}_{17}\text{A'}$ . [55°]. (135°) at 25 mm.; (231°) at 760 mm. On distillation it is partially converted into cyanuric acid (Arth, *C. R.* 102, 977).

Bornyl carbamate v. p. 523.

Menthyl carbamate v. MENTHOL.

CARBAMIDE v. UREA.

CARBAMIDO- v. URAMIDO-.

CARBAMINES. Carbylamines. Iso-nitriles. Compounds of the formula  $\text{R.N.C.}$

Formation.—1. By distilling primary monamines with chloroform and alcoholic potash:  $\text{RNH}_2 + \text{CHCl}_3 + 3\text{KOH} = 3\text{KCl} + \text{RNC} + 3\text{H}_2\text{O}$  (Hofmann, *A.* 144, 114; 146, 107).—2. By treating an alkyl iodide (1 mol.) with silver cyanide (2 mols.) a double salt  $\text{RNC}_2\text{AgCy}$  is formed; on distilling this compound with conc. aqueous  $\text{KCy}$  there is formed  $\text{KC}_2\text{AgCy}$  and the carbamine passes over (Gautier, *A.* 146, 119; 149, 29, 155; 151, 239).  $\text{HgCy}_2$  and  $\text{ZnCy}_2$  may also be used in preparing carbamines (Calmels, *B.* [2] 43, 82).—3. In small quantity in preparing nitriles by distilling potassium alkyl sulphates with potassium cyanide.—4. By distilling the compounds of thio-carbimides with tri-ethylphosphine (Hofmann, *B.* 3, 766; *Z.* 7, 29).

Properties.—Volatile stinking poisonous oils.

Reactions.—1. Alkalis have no action.—2. Mineral acids instantly convert them into alkylamines and formic acid:  $\text{RNC} + 2\text{H}_2\text{O} = \text{RNH}_2 + \text{H.CO.H}$ . Water at 180° acts similarly. 3. Dry  $\text{HCl}$  forms a compound, quickly decomposed by water as in 2.—4. Organic acids form alkyl-formamides.—5.  $\text{EtI}$  forms a compound (difference from nitriles).—6.  $\text{HgO}$  oxidises them to alkyl cyanates  $\text{R.N.CO}$ , alkyl-formamides being also formed (Gautier, *A.* 149, 311).

CARBAMINE-CYANIDE or CARBAMINE-CYANAMIDE so called is described as  $\text{Amido-di-cyanic acid}$ . Its derivatives are described as ETHYL-CARBIMIDO-UREA, CARBIMIDO-ETHYL-UREA, &c.

CARBANIL v. PHENYL CYANATE.

CARBANILIC ACID v. PHENYL-CARBAMIC ACID.

CARBANILIDE v. s-DI-PHENYL-UREA.

CARBANILIDO- v. PHENYL-URAMIDO-.

CARBAZOLE  $\text{C}_{12}\text{H}_9\text{N}$  i.e.  $\text{C}_6\text{H}_4\text{N} \cdot \text{C}_6\text{H}_5$

Mol. w. 167. [258°]. (352° cor.). V.D. 5.86 (calc. 585). S. (alcohol 32 at 14°; 8.88 at 78°. S. (toluene) 55 at 18.5; 5.46 at 100° (Bechi, *B.* 12, 1978).

Occurrence.—Among the products of the distillation of coal tar; hence it occurs in crude anthracene (Graebe a. Glaser, *B.* 5, 12, 876; *A.* 163, 313; 167, 125; 174, 180; 202, 21; Zeidler, *A.* 191, 297).

Formation.—1. By passing vapour of aniline or diphenylamine through a red-hot tube.—2. From imido-di-phenyl sulphide (thio-diphenyl-amine) by boiling  $\text{HN} \cdot \text{C}_6\text{H}_4 \cdot \text{S}$  with freshly reduced copper for 2 or 3 hours; the yield is about 60 p.c. (Goske, *B.* 20, 233).

Properties.—White laminae or tables. Easily sublimable. A solution in conc.  $\text{H}_2\text{SO}_4$  is turned green by  $\text{HNO}_3$ . May be distilled over red-hot zinc-dust without change. Although an imide, it forms a compound with picric acid and its acetyl derivative is obtained with difficulty.

Reactions.—1. It is not affected by conc.  $\text{HClAq}$  or alcoholic  $\text{KOH}$  even at 300°. Cold conc.  $\text{H}_2\text{SO}_4$  dissolves it without change, but at 100° a di-sulphonic acid results.—2.  $\text{HNO}_3$  forms nitro-compounds.—3. Sodium-amalgam does not reduce it in alcoholic solution, but  $\text{HI}$  and  $\text{P}$  at 210° reduce it to carbazoline  $\text{C}_{12}\text{H}_{11}\text{N}$ .—4. By exhaustive chlorination with  $\text{SbCl}_5$  it yields per-chloro-diphenyl or per-chlorobenzene according to circumstances as yet undetermined (Merz a. Weith, *B.* 16, 2875).—5. By heating with oxalic acid the compound  $\text{C}_{12}\text{H}_9\text{N}_3\text{O}$  or  $\text{HO.C}(\text{C}_6\text{H}_4\text{N})_2$  is obtained.

It forms minute crystals which very readily yield blue solutions (carbazole blue) on oxidation (Suida, *B.* 12, 1403; Bamberger a. Müller, *B.* 20, 1905).

Potassium derivative  $\text{C}_{12}\text{H}_9\text{NK}$ . From carbazole and  $\text{KOH}$  at 230°. Picric acid compound  $\text{C}_{12}\text{H}_9\text{N.C}_6\text{H}_2(\text{NO}_2)_3\text{O.H}$ . [182°]. From carbazole (1 pt.) and picric acid (1½ pts.) in toluene. Red prisms; v. sl. sol. cold benzene or alcohol. Decomposed by a large quantity of alcohol, by water, and by alkalis.

Nitrosamine  $\text{C}_{12}\text{H}_9\text{N.NO}$ . [82°]. Nitrous acid in an alcoholic solution of carbazole forms mono- and di-nitro-carbazole. If carbazole (3 g.) be mixed with acetic acid (60 g. of S.G. 1.04) and ether (60 g.) be poured in, on adding  $\text{KNO}_3$  the nitrosamine is dissolved in the ether as fast as it is formed, and crystallises out on evaporation. Long flat golden needles. Soluble in ether,  $\text{CS}_2$ , chloroform, glacial acetic acid and benzene. It is decomposed if heated with alcohol mixed with an acid, carbazole being regenerated. Alcoholic  $\text{KOH}$  turns it blood-red. Reducing agents regenerate carbazole. Conc.  $\text{H}_2\text{SO}_4$  gives a dark-green colour (Zeidler, *A.* 191, 305).

Acetyl derivative  $\text{C}_{12}\text{H}_9\text{NAc}$ . [69°]. (above 360°). From carbazole and  $\text{Ac}_2\text{O}$  at 250°. Slender needles (from water); v. sl. sol. water, v. e. sol. alcohol. Erdmann's solution does not turn it green. Its picric acid compound is orange.

*References.* — BROMO-, CHLORO-, NITRO-, METHYL-, and ETHYL-, CARBAZOLE.

**CARBAZOLE TETRAHYDRIDE**  $C_{12}H_{11}N$ . [120°]. (c. 328°). Formed, together with hydrogen, by heating carbazoline hydrochloride at 800°. Crystallises from alcohol. V. e. sol. alcohol, insol. water. Does not combine with acids. Reduced by HI and P to carbazoline. The picric acid compound  $C_{12}H_9N_3O_6$  forms brown laminae.

**CARBAZOLE  $\nu$ -CARBOXYLIC ACID**  $C_{12}H_9NO_2$  i.e.  $C_{12}H_9N.CO_2H$ . [272°]. From potassium carbazole and  $CO_2$  at 270°. Micaceous scales or flattened prisms with faint blue fluorescence; insol. water, sl. sol. cold alcohol (Ciamician & Silber, G. 12, 272).

**CARBAZOLINE**  $C_{12}H_9N$ . Carbazole hexahydrate. [99°]. (297° i. V.). V. D. 6.13 (5.99 calc.). Formed by heating carbazole (3 pts.) with (12 pts. of)  $HIAg$  (127°) and amorphous P (1 pt.) at 220°. White needles (from alcohol); may be sublimed; volatile with steam; v. e. sol. alcohol and ether, v. sl. sol. water. HI and P at 339° reduce it to diphenyl decaldehyde  $C_{12}H_{10}$ . Does not combine with picric acid.

Salts.— $BHCl$ : v. e. sol. water.— $BHBr$ : tables.— $BHI$ .

*Acetyl derivative*  $C_{12}H_9N.AC$ . [98°]. From carbazoline and  $Ac_2O$  at 110°. Needles (from alcohol).

**CARBIDES.** Compounds of carbon with one other more positive element. A carbide of iron  $Fe_3C$  probably exists in cold rolled steel; other carbides of this metal are described, but their existence is doubtful. Silver is said to form three carbides,  $Ag_2C$ ,  $Ag_3C$ , and  $AgC$ . Nickel takes up a small quantity of carbon when strongly heated with charcoal, but no definite compound has yet been prepared. We have very little definite information regarding this class of compounds (v. Iridium, Iridium, Nickel, Palladium, Platinum, and Silver). M. M. P. M.

**CARBIMIDE** v. CYANIC ACID.

**CARBIMIDO-ALLYL-THIO-UREA**  $C_5H_9N_3S$  i.e.  $SC<\begin{smallmatrix} NC_2H_5 \\ NH \end{smallmatrix}>C:NH$  or  $C_4H_9N_3S.N:C:NH$ .

*Allyl-thio-carbamine-cyanide.* Formed, as the crystalline sodium salt, by mixing allyl-thio-carbimide and sodium cyanamide. Decomposed by acids into its constituents (Wunderlich, B. 19, 448).

**CARBIMID-AMIDO-BENZOIC ACID** is Guanido-di-benzoic acid v. p. 157.

**CARBIMIDAMIDO-BENZOYL** v. OXY-QUINAZOLINE and p. 155.

**CARBIMIDO-CYANAMIDE** v. AMIDO-DICYANIC ACID, p. 163.

**CARBIMIDO-ETHYL-THIO-UREA**  $C_4H_9N_3S$  i.e.  $SC<\begin{smallmatrix} NEt \\ NH \end{smallmatrix}>C:NH$  or  $EtHN.CO.N:C:NH$ .

*Ethyl-thio-carbamine-cyanide.* Formed, as the crystalline sodium salt, by mixing ethyl-thio-carbimide and sodium cyanamide. Decomposed by acids into its constituents (Wunderlich, B. 19, 448).

**CARBIMIDO-ETHYL-UREA**  $C_4H_9N_3O$  i.e.  $OC<\begin{smallmatrix} NEt \\ NH \end{smallmatrix}>C:NH$  or  $EtHN.CO.N:C:NH$ . *Ethyl-carbamine-cyanide.* Formed, as the crystalline sodium salt, by mixing ethyl cyanate and sodium cyanamide. Decomposed into its con-

stituents by acids. Forms a green crystalline copper compound (Wunderlich, B. 19, 448).

**CARBIMIDO-METHYL-THIO-UREA**

$C_4H_9N_3S$  i.e.  $SC<\begin{smallmatrix} NM \\ NH \end{smallmatrix}>C:NH$  or

$MeHN.CO.N:C:NH$ . *Methyl-thio-carbamine-cyanide.* Formed, as the crystalline sodium salt, by mixing methyl-thio-carbimide and sodium cyanamide. Decomposed by acids into its constituents (Wunderlich, B. 19, 448).

• **CARBIMIDO-PHENYL-THIO-UREA**

$C_8H_9N_3S$  i.e.  $SC<\begin{smallmatrix} NPh \\ NH \end{smallmatrix}>C:NH$  or

$PhNH.CO.N:C:NH$ . *Phenyl-thio-carbamine-cyanide.* Formed, as the crystalline sodium salt, by mixing phenyl-thio-carbimide and sodium cyanamide. Decomposed by acids into its constituents (Wunderlich, B. 19, 448).

**DI-CARBIN-TETRA-CARBOXYLIC ACID** v.

ETHYLENE-TETRA-CARBOXYLIC ACID.

**CARBINOL.** A name given by Kolbe to methyl alcohol, but used only in describing alcohols derived therefrom by displacement of hydrogen of its methyl by one or more alkyls. Cf. ALCOHOLS.

**CARBINYL.** The corresponding term for the alcohol radicals of the alkyl-carbinols; thus,  $Me_3C$  may be called tri-methyl-carbinyl.

**CARBO-ACETO-ACETIC ETHER** v. p. 20.

**CARBO-ALLYL-PHENYL-AMIDE** v. PHENYL-

ALLYL-CYANAMIDE.

**CARBO-DI-BUTYL-DI-PHENYL-IMIDE** v.

DI-BUTYL-DI-PHENYL-CYANAMIDE.

**CARBO-ISO-BUTYRALDINE**  $C_8H_{11}N_2S_2$  i.e.  $(NH_2)CS.S.N(C_2H_5)_2$ . [91°]. From iso-butyraldehyde,  $CS_2$ , and aqueous  $NH_3$ . Prisms, insol. water, sol. alcohol (Pfeiffer, B. 6, 701).

**CARBO-CAPRO-LACTONIC ACID** v. *Lactone of OXY-PROPYL-SUCCINIC ACID.*

*Di-carbo-capro-lactonic acid* v. *Lactone of OXY-PENTANE-2,5-DI-CARBOXYLIC ACID.*

**CARBOCINCHOMERONIC ACID** is PYRIDINE TRI-CARBOXYLIC ACID.

**CARBO-GLUCONIC ACID**  $C_6H_{10}O_8$ . An amorphous acid whose  $NH_2$  salt is obtained by treating glucose or cane-sugar with aqueous  $HCN$  (Schützenberger, Bl. [2] 36, 144).

**CARBO-DI-GLYCOLLIC ETHER** v. GLYCOLLIC ACID.

**CARBOHOMOPYRROLIC ACID** v. METHYL-PYRROL-CARBOXYLIC ACID.

**CARBOHYDRATES.** A term applied to compounds which may be represented by the formula  $C_x(H_2O)_y$ , where  $x$  is 5, 6, or 12, and  $y$  is 5, 6 or 11, and to compounds derived from several such molecules by abstraction of water. They are non-volatile solids, and the non-saccharine members of the group may be converted by boiling dilute acids into a sugar, usually glucose (dextrose). They contain hydroxyl. On oxidation they frequently give rise to oxalic, racemic, saccharic, and mucic acids. Most of them are optically active. Cellulose is insoluble in water; the gums dissolve, or at least swell up, in water, but are ppd. by alcohol. Sugars are soluble in water, are not reppd. by alcohol, and have a sweet taste. Iodine turns starch blue, and affects cellulose in the same way after it has been treated with a dehydrating agent. The carbohydrates vary also in their behaviour towards alkaline copper solutions, and as regards

fermentation by yeast. They are described in the articles ARABIC ACID, CELLULOSE, DEXTRIN, STARCH, SUGAR, ETC.

**CARBOLIC ACID** *v.* PHENOL.

**CARBO-MESYL** *v.* METHYL-OXINDOLE.

**CARBO-DI-NAPHTHYL-IMIDE** *v.* DI-NAPHTHYL-CYANAMIDE.

**CARBON GROUP OF ELEMENTS.**—*Carbon and Silicon.* Of these elements, carbon occurs in the free state in the forms of diamond, graphite, and amorphous carbon; silicon is not known as such in nature, but combined with oxygen it is one of the most widely-distributed elements. Diamond was regarded by Newton as a combustible body because of its great refractive power: in 1694 the Florentine academicians succeeded in burning small pieces of diamond; and in the early years of this century Davy proved it to be pure carbon. In early times graphite was thought to be very similar to lead; hence the

name *plumbago*; for a time it was confused with molybdenum-glance, but in 1799 Scheele proved it to be closely related to coal in its composition. It is only in somewhat recent times that approximately pure graphite has been obtained. Charcoal is the commonest form of impure amorphous carbon; this modification of carbon can be obtained approximately pure only with considerable difficulty.

After the earth had been proved to be metallic oxides in 1807, it was generally supposed that the common earth-like body silica would also be found to contain oxygen and a metal. In 1823 Berzelius decomposed silica and obtained the non-metal silicon, in the form of a brown amorphous powder. A good many years later Deville prepared crystallised silicon in two forms, one more or less resembling diamond, and the other, graphite. The leading properties of the two elements are as follows:—

	CARBON.	SILICON.
<i>Atomic weights</i>	11.97	28

Many compounds of each element have been gasified. Molecular weights unknown:  
(?) probably greater than  $C_2$  and  $Si_2$ .

<i>Melting-points</i>	Does not melt at any temperature hitherto attained.	1,100°–1,300° (uncertain).
<i>Specific gravities</i> (approximate)	Diamond 3.5; graphite 2.25; amorphous 1.5–1.9.	Graphitoidal 2.2–2.5 (doubtful).
<i>Specific heats</i>	0.46 (at about 1000°).	0.203 (at about 250°)

The specific heat of either element increases rapidly as temperature increases from  $-50^\circ$ : the rate of this increase is, however, very small after about  $500^\circ$  for carbon and about  $150^\circ$  for silicon. The specific heats of diamond and graphite vary considerably at temperatures below about  $600^\circ$ , but from this point upwards the values are practically identical.

<i>Atomic weight</i>

		4	5,230
			5,410

Silicic acid shows no constant neutralisation-point. The quantity of heat produced is a hyperbolic function of the quantity of soda added, and approaches a probable maximum of 6,300 gram-units for one formula-weight of  $SiO_2$  (*v.* SILICATES).

<i>Physical properties</i>	<i>Diamond</i> : hardest known substance; crystallises in regular forms, octahedral predominating; bad conductor of electricity; refractive index large ( $\mu_D = 2.430$ ); lustre very marked; usually colourless and transparent, but sometimes green, brown, or yellow.	<i>Adamantine</i> : very hard, scratches glass; dark iron-grey colour, reddish by reflected light; crystallises in forms derived from a rhombic octahedron. <i>Graphitoidal</i> : softer than adamantine but scratches glass; may be pulverised; metal-like lustre, leaden-

TABLE—cont.

	CARBON.	SILICON.
	<p><b>Graphite:</b> crystallises in hexagonal forms; good conductor of electricity; tough and difficult to pulverise; grey, metal-like appearance.</p> <p><b>Amorphous:</b> black powder; very porous, absorbs large quantities of gases and of many colouring matters from solutions.</p>	<p>grey colour; crystallises in leaflets composed of octahedra; good conductor of electricity.</p> <p><b>Amorphous:</b> brown powder; heated out of contact with air to high temperature it contracts and becomes crystalline; bad conductor of electricity; dissolves in molten Al or Zn and crystallises out on cooling.</p>
Occurrence and preparation	<p>The three forms occur in nature, but neither graphite nor amorphous pure; constituent element of all animal and vegetable matter; carbonates very widely distributed; graphite prepared by dissolving amorphous in molten iron, or by decomposing by heat the CN compounds in the mother liquor of soda manufacture, &amp;c.: approximately pure amorphous, prepared by washing sugar-charcoal in acid, alkali, and water, and strongly heating in chlorine; or by decomposing <math>\text{CO}_2</math> by Na, &amp;c.</p>	<p>Very widely distributed as silicates of Ca, Mg, Fe, Al, &amp;c.; amorphous obtained by action of K on hot <math>\text{SiCl}_4</math>, <math>\text{SiF}_4</math>, or <math>\text{K}_2\text{SiF}_6</math>; graphitoid obtained by melting Al with <math>\text{K}_2\text{SiO}_3</math> and cryolite, or by decomposing <math>\text{SiCl}_4</math> at a high temperature by Na; adamantine obtained by melting Zn with <math>\text{K}_2\text{SiF}_6</math> and Na.</p>
Chemical properties.	<p>Allotropy marked. Diamond heated by powerful battery in absence of oxygen gets grey-black and coke-like but does not volatilise; heated in air combustion begins at <math>950^\circ</math>–<math>1000^\circ</math>. Graphite not affected at any temperature in absence of oxygen; oxidised by repeated treatment with <math>\text{KClO}_3</math> and <math>\text{HNO}_3</math> to graphitic acid <math>\text{C}_6\text{H}_6\text{O}_6</math> (or <math>\text{O}_6</math>), a yellow solid, sol. water, acting towards alkaline bases like a feeble acid. Amorphous burns easily in air; combines with H at a very high temperature to form <math>\text{C}_2\text{H}_2</math>; also combines directly with S to form <math>\text{CS}_2</math>, with O to form CO and <math>\text{CO}_2</math>, and under special conditions with N to form <math>\text{C}_2\text{N}_2</math>; compounds with halogens formed indirectly; combines directly with Ir, Fe, Ni, Pd, Pt, Ag, and perhaps some other metals. Carbon a negative element; does not form salts by replacing H of acids; <math>\text{CO}_2</math> an anhydride; an aqueous solution of <math>\text{CO}_2</math> probably contains the dibasic acid <math>\text{H}_2\text{CO}_3</math>, salts of this acid well marked; <math>\text{H}_2\text{CS}_3</math> prepared. Atom of C is tetravalent; C atoms tend to combine with each other; vast number of compounds produced by addition of other atoms to groups of C atoms.</p>	<p>Allotropy marked. Amorphous Si burns easily in air to <math>\text{SiO}_2</math>; graphitoid does not oxidise when heated; adamantine not even at a white heat in oxygen; adamantine Si oxidised at red heat in <math>\text{CO}_2</math> (giving <math>\text{CO} + \text{SiO}_2</math>), also by strongly heating with <math>\text{K}_2\text{CO}_3</math> or <math>\text{Na}_2\text{CO}_3</math> (giving <math>\text{CO} + \text{SiO}_2 + \text{C}</math>), but not changed by molten <math>\text{KHSO}_4</math>, or by heating with <math>\text{KNO}_3</math> if temp. at which that salt decomposes is not reached. Amorphous Si soluble in <math>\text{HFAq}</math> giving <math>\text{H}_2\text{SiF}_6\text{Aq}</math> and hydrogen, also in strong hot potash ley giving <math>\text{K}_2\text{SiO}_3\text{Aq}</math> and hydrogen; adamantine Si insoluble in <math>\text{HFAq}</math> and hot alkali solutions. Si does not directly combine with H, <math>\text{SiH}_4</math> produced by action of <math>\text{HClAq}</math> on compound of Si and Mg; combines with S at high temperature to form <math>\text{SiS}_2</math>; with O to form <math>\text{SiO}_2</math>; with Cl, Br, or I, to form <math>\text{SiCl}_4</math>, <math>\text{SiBr}_4</math>, or <math>\text{SiI}_4</math>; and with N at white heat to form <math>\text{Si}_3\text{N}_4</math>; combines directly with Al, Cu, Fe, Mg, Mn, Ni, Pt, and perhaps some other metals. <math>\text{SiO}_2</math> an anhydride; probable existence of several silicic acids; <math>\text{SiO}(\text{OH})_2</math> probably present in solution obtained by neutralising <math>\text{K}_2\text{SiO}_3\text{Aq}</math> by <math>\text{HClAq}</math> and dialysing; this solution very readily gelatinises. Atom of Si is tetravalent, and to some extent at least, atoms of Si tend to combine together and form groups which combine with other atoms, forming molecules similar to those of the organic compounds.</p>

*General formula and characters of compounds.*

MO, MO<sub>2</sub>, MS<sub>2</sub>, (SiO unknown, ? CS and C<sub>2</sub>S<sub>2</sub>); MO<sub>2</sub>H<sub>2</sub> (neither known except (?) in aqueous solution, *v.* Carbon and Silicon), OS<sub>2</sub>H<sub>2</sub>; MH<sub>4</sub>; C<sub>2</sub>H<sub>2n+2</sub>, C<sub>2</sub>H<sub>2n</sub>, C<sub>2</sub>H<sub>2n-2</sub>, C<sub>2</sub>H<sub>2n-4</sub>, &c., &c., and a vast number of derivatives; MX<sub>4</sub> (X=Cl, Br, I, or in case of Si also =F), M<sub>2</sub>X<sub>6</sub> (X=Cl, Br, or I where M=Si, X=Cl or Br where M=C), C<sub>2</sub>Cl<sub>4</sub>, C<sub>2</sub>Br<sub>4</sub>, &c.; SiF<sub>4</sub>H<sub>2</sub>; CH<sub>3</sub>Cl, CH<sub>2</sub>Cl<sub>2</sub>, CHCl<sub>3</sub>, SiHCl<sub>3</sub>, SiH<sub>2</sub>, &c.; C<sub>2</sub>N<sub>2</sub>, ONH and salts, C<sub>2</sub>N<sub>2</sub>FeH<sub>2</sub> and salts, C<sub>2</sub>N<sub>2</sub>FeH<sub>2</sub> and salts, C<sub>2</sub>N<sub>2</sub>NOFeH<sub>2</sub> and salts, &c., &c.; Si<sub>2</sub>N<sub>2</sub>, &c. The compounds of C and Si exhibit considerable differences in their properties; CO and CO<sub>2</sub> are gases, SiO<sub>2</sub> is a very fixed solid; CS<sub>2</sub> is a liquid, SiS<sub>2</sub> a solid; CCl<sub>4</sub> is not acted on by water, SiCl<sub>4</sub> is at once decomposed into SiO<sub>2</sub> and HCl; Si readily forms a fluoride and also a double fluoride with hydrogen, no corresponding compounds of C are known; CH<sub>4</sub> is a stable gas, SiH<sub>4</sub> is oxidised by mere contact with air and is easily decomposed by heat (at 400°); Si (amorphous) dissolves in potash evolving hydrogen and forming a silicate, carbon is unacted on by alkalis. Both elements form many compounds with H and O (alcohols, ethers, acids &c.), the composition of which is similar, in some cases the properties of the Si compounds closely resemble those of C, *e.g.* C(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>H and Si(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>H, C(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>OH and Si(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>OH; but in other cases the properties of the two classes of compounds differ much, *e.g.* CH<sub>3</sub>CO<sub>2</sub>H and C<sub>2</sub>H<sub>5</sub>CO<sub>2</sub>H are liquids soluble in water, but CH<sub>3</sub>SiO<sub>2</sub>H and C<sub>2</sub>H<sub>5</sub>SiO<sub>2</sub>H are amorphous solids insoluble in water. Many silicates and carbonates are isomorphous. Silicates, except those of the alkali metals, are insoluble in water, and most of them are with difficulty decomposed by acids; the normal carbonates of the alkali metals are soluble in water, other normal carbonates are insoluble; aqueous solutions of acid carbonates are generally easily decomposed by heat yielding either normal or basic carbonates; the normal carbonates of the alkali metals are not decomposed by heat alone, other normal carbonates are decomposed into metallic oxide and CO<sub>2</sub>.

Group IV. of the elements, as the elements are classified by the application of the periodic law, contains the following:—

	Series					
Even	2	4	6	8	10	12
	C	Ti	Zr	Ce	—	Th
Odd	3	5	7	9	11	
	Si	Ge	Sn	—	Pb	

The metals titanium, zirconium, and germanium show considerable analogies with tin; cerium and thorium are usually classed together among the rarer earth-metals, and lead is generally considered apart from other metals; nevertheless, there are well-marked analogies between all the elements which comprise Group IV. of the periodic system. Titanium is an amorphous body closely resembling amorphous silicon; it forms the compounds TiF<sub>4</sub>, TiCl<sub>4</sub>, TiBr<sub>4</sub>, TiI<sub>4</sub>, Ti<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub> (probably TiO(OH) and Ti(OH)<sub>4</sub>), Ti<sub>2</sub>O<sub>3</sub>, Ti<sub>3</sub>N<sub>2</sub>, &c.; titanates are known (M<sub>2</sub>TiO<sub>4</sub>), many of them isomorphous with silicates and carbonates. Ti is more metallic than

C or Si, it forms a sulphate Ti(SO<sub>4</sub>)<sub>2</sub>, and other salts wherein the hydrogen of acids is replaced by titanium. Zirconium again is more decidedly metallic than titanium; it forms a series of well-marked salts Zr(SO<sub>4</sub>)<sub>2</sub>, Zr(NO<sub>3</sub>)<sub>2</sub>, &c., &c. On the other hand Zr resembles C and Si in that it has been obtained both as an amorphous powder, and also in crystals which resemble Si in their behaviour towards acids; zirconates (M<sub>2</sub>ZrO<sub>4</sub>) are also known. Germanium forms oxides, chlorides, and sulphides, &c. (GeX and GeX<sub>2</sub>, X=O=S=Cl<sub>2</sub>), resembling those of Sn; it is, however, more markedly non-metallic in its chemical functions than Sn; physically Ge is decidedly metallic. Cerium forms two oxides Ce<sub>2</sub>O<sub>3</sub> and CeO<sub>2</sub>; the former dissolves in acids forming a series of salts of which Ce<sub>2</sub>BSO<sub>4</sub> is a type; CeO<sub>2</sub> is a peroxide, it dissolves in HCl with evolution of Cl and formation of CeCl<sub>3</sub>, but a sulphate Ce(SO<sub>4</sub>)<sub>2</sub> is known corresponding to the sulphates of Ti and Zr. Ce also forms a fluoride CeF<sub>3</sub>, a double fluoride 3KF.2CeF<sub>3</sub>, and a chloride CeCl<sub>3</sub>. Thorium again approaches more closely than cerium to Zr and Ti; it is a dark-coloured amorphous powder resembling Si, but more soluble in acids than Si, Zr, or Ti; it forms the compounds ThCl<sub>4</sub>, ThF<sub>4</sub>, K<sub>2</sub>ThF<sub>6</sub>, ThO<sub>2</sub>, &c.; the sulphate is Th(SO<sub>4</sub>)<sub>2</sub>, and other analogous salts are known. Tin forms the two oxides and chlorides SnO and SnO<sub>2</sub>, SnCl<sub>2</sub> and SnCl<sub>4</sub>; the hydrates of SnO<sub>2</sub> are feeble acids, producing stannates (M<sub>2</sub>SnO<sub>4</sub>) and metastannates (M<sub>2</sub>Sn<sub>2</sub>O<sub>7</sub>), both of which are easily decomposed by dilute acids or by heat. Both the stannous salts *e.g.* SnSO<sub>4</sub>, and the stannic salts *e.g.* Sn(SO<sub>4</sub>)<sub>2</sub>, are well-marked compounds. Lead is decidedly metallic in its character; it forms four oxides PbO, Pb<sub>2</sub>O, Pb<sub>3</sub>O<sub>4</sub>, and PbO<sub>2</sub>; the last is a peroxide, and it may also be regarded as an anhydride inasmuch as plumbates (M<sub>2</sub>PbO<sub>4</sub>) exist, but these salts are very unstable and easily decomposed. The best-marked salts of lead are derived from the oxide PbO, *e.g.* PbCl<sub>2</sub>, Pb<sub>2</sub>NO<sub>3</sub>, PbSO<sub>4</sub>, &c.; PbCl<sub>4</sub> has not been obtained pure, but this series of salts is represented by the tetramethide Pb(CH<sub>3</sub>)<sub>4</sub>, which is stable as a gas. The atoms of all the elements of Group IV., so far as evidence has been obtained, are tetravalent. Looking at the properties of these elements as a whole, it may be said that carbon is to a considerable extent set apart from the others, but that it is more closely allied to silicon than to any other member of the group; that titanium and zirconium are closely related; and that tin and lead, while showing distinct analogies with the rest of the group, are yet each characterised by properties which mark them off from the other elements. Not much can yet be said regarding cerium and thorium; they require further study.

For more details and descriptions of the various elements see the articles on these elements; also *v.* TITANIUM GROUP OF ELEMENTS; also *v.* CARBONATES, NITRATES, SULPHATES, &c. In some of their physical properties carbon and silicon, especially the latter, resemble boron, but boron must be classed with those elements the atoms of which are trivalent: *v.* BORON.

M. M. P. M.

CARBON C. At. w. 11.97. Mol. w. unknown; element has not been gasified. S.G. diamond

18° 3-514 (Schrötter, *Sitz. W.* 63, (2nd pt.) 462),  
 2° 2-518 (Baumhauer, *Ar. N.* 8, 1). S.G. graphite 2-11 to 2-26 (Kenngott, Brodie, Mène; *Sitz. W.* 13, 469; A. 114, 77; *C. R.* 64, 104). S.G. amorphous charcoal 1-45 to 1-7 (v. Viollette, *A. Ch.* [3] 39, 291). S.G. hard gas-coke 2-356 (Marchand a. Meyer). S.H. about 5 at 1000° (v. *infra*). C.E. (diamond, linear at 40°) 00000118; (diamond, cub. at 49°) 00000354; (graphite, linear at 40°) 00000786; (Eizeau, *C. R.* 62, 1133; 68, 1125).  $\mu_n = 2.46$ ,  $\mu_r = 2.479$ , for diamond (Schröter, *P.* 112, 588). E.C. graphite, 082 (Hg at 0° = 1) [varies much for different specimens] (Muraoka, *W.* 13, 307). E.C. hard gas-coke, 01 (Hg at 0° = 1) (Muraoka, *l.c.*). Crystalline form; diamond, regular octahedra and forms derived therefrom; graphite, hexagonal forms chiefly rhombohedral (Kenngott, *Sitz. W.* 13, 469); Nordenskiöld (*P.* 96, 100) observed monoclinic crystals in graphite from Finland. H.C. [C,O] = 96,960 for amorphous C (*Th.* 1, 411); 93,350 for diamond, and 93,560 for graphite (Favre a. Silbermann, *A. Ch.* [3] 33, 411). Emission-spectrum observed by passing sparks through pure CO or C<sub>2</sub>, is characterised by a double line 6583 and 577-5, three sharp lines 5150-5, 5144-2, 5133, and a band 4266 (Ångström a. Thalen, *Nov. Act. Ups.* 9 [1875]). Besides these, and many other less marked, lines, Liveing a. Dewar describe the arc-spectrum as showing the following marked lines, 3919-3, 2837-2, 2836-3, 2511-9, 2509-9, 2296-5 (*Pr.* 30, 152, 494; 33, 403; 34, 123, 418). A very different spectrum—the band-spectrum—is observed at the base of a candle or gas flame, also in cyanogen burnt in O, or by passing sparks through CN, CO at increased pressure, CS<sub>2</sub>, &c.; the most characteristic band is 5633, 5161, and 4736. There has been much discussion as to whether this spectrum is that of C or of a hydrocarbon (v. *D. A.* 1880, 254). Three allotropic forms of carbon are known; diamond, graphite, and amorphous carbon.

The diamond was regarded by Newton as a combustible body because of its high refractive power; in 1691 diamond was burnt by the Florentine Academicians; Lavoisier found that CO<sub>2</sub> is produced when diamond is burnt, and Davy showed that diamond is pure carbon. Lavoisier, about 1780, recognised that carbonic acid (then called fixed air) was a compound of O and the element which is the essential element of coal; to this element he gave the name *carbone*. Graphite was long considered to be a kind of lead; Scheele, in 1799, showed it to be closely related to coal; he regarded it as a compound of iron and carbon, but Kastner proved that the iron found in graphite was only an impurity, and that pure graphite is a form of carbon.

**Occurrence.**—Carbon occurs as diamond and graphite, the former is pure, the latter sometimes approximately pure, carbon; many compounds of C occur in nature; the chief are CO<sub>2</sub> in the air and all waters, mineral carbonates e.g. of Ca and Mg, and compounds with H, O, N, and sometimes P and S, in all animal and vegetable organisms. Diamonds are found in India, Borneo, Brazil, the Cape, &c.; graphite, in Cumberland, California, Siberia, &c. Berthelot

(*C. R.* 73, 494) found graphite in a meteorite which fell near Melbourne (Australia); and Fletcher found a cubic form of graphite in a meteorite from Western Australia (*Mineralog. Mag.*, Jan. 1887). Graphite is found both amorphous and *foliated*. Coal, anthracite, peat, &c., contain from 50 to 95 p.c. of carbon.

**Formation.**—Many attempts have been made to form diamond; none has been certainly successful (v. Liebig, *Agriculturchemie* [1840] 85; Wilson, *J.* 1850, 697; Favre, *J.* 1856, 828 [from CCl<sub>4</sub>]; Despretz, *C. R.* 37, 369 [electric current for a month from Pt to C pole]; Simmler, *P.* 105, 466 [crystallisation from liquid CO<sub>2</sub>]; Lionet, *C. R.* 63, 213 [from CS<sub>2</sub>]; Chancelorlois, *C. C.* 1866, 1037 [oxidation of hydrocarbon]; Rossi, *C. R.* 63, 408; Hannay, *Tr.* 30, 188 a, 450 [action of Mg, and Li, on gaseous hydrocarbons mixed with N-containing compounds at very high temperatures and pressures]; Marsden, *Pr. E.* 11, 20 [by dissolving amorphous C in molten Ag]. Graphite is formed:—1. By heating charcoal with molten iron, and dissolving out the Fe by HCl and HNO<sub>3</sub> Aq.—2. By the slow decomposition of HCN Aq, and boiling the product with HNO<sub>3</sub> Aq (Wagner, *J. C. T.* 1869, 230).—3. By evaporating the mother liquors obtained in making soda; these contain CN compounds which are decomposed at a certain concentration of the liquid with formation of NH<sub>3</sub> and graphite (Pauli, *D. P. J.* 161, 129; Schaffner, *W. J.* 1860, 250).—4. By leading CO over Fe<sub>2</sub>O<sub>3</sub> at 300°–400° (Grüner, *C. R.* 73, 28; Stiegl, *B.* 6, 392). Amorphous C is also formed (Berthelot, *C. R.* 73, 494).—5. By the decomposition of CS<sub>2</sub> at high temperatures. 6. By leading CCl<sub>4</sub> over molten pig-iron (Deville, *A. Ch.* [3] 49, 72). Amorphous carbon is formed in many ways:—1. By heating wood, coal, or almost any animal or vegetable matter, out of contact with air, to a high temperature.—2. By the incomplete combustion of wax, tallow, oil, or other combustible compounds of C and H.—3. By decomposing, at a very high temperature and out of contact with air, the gaseous C compounds obtained in the production of gas from coal; the carbon thus obtained is very hard (v. *Properties*).

**Preparation.**—Pure graphite is obtained by intimately mixing 14 parts of finely powdered foliated graphite with 1 part KClO<sub>3</sub> and 2 parts conc. H<sub>2</sub>SO<sub>4</sub>, heating on the water-bath so long as Cl comes off, washing repeatedly with hot water, drying, and heating to remove H<sub>2</sub>SO<sub>4</sub>; if the graphite contains silica it is treated with Na<sup>+</sup> and H<sub>2</sub>SO<sub>4</sub>, besides treatment with KClO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> (Brodie, *T.* 1860, 1; v. also Winckler, *J. pr.* 98, 243; Stin. 1, B. 6, 391).

Amorphous carbon is prepared approximately pure by strongly heating cane sugar in a closed Pt crucible, boiling the charcoal thus produced with (1) conc. HCl Aq, (2) KOH Aq, (3) water, drying, heating to full redness in a stream of dry Cl and allowing to cool in the same; H is removed as HCl, O as CO, also traces of SiO<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub>, &c. as SiCl<sub>4</sub>, FeCl<sub>3</sub>, AlCl<sub>3</sub>, &c. The soot from semi-burnt turpentine oil, after treatment with ether, and heating to a high temperature in a closed vessel, is approximately pure carbon. It seems to be impossible to obtain finely divided amorphous C quite free from gases

such as H, O, or Cl; even when purified as described it retains traces of Cl, this may be removed by strongly heating in connection with a Sprengel pump, but on exposure to the air considerable quantities of O, CO<sub>2</sub>, &c. are quickly absorbed. The absorbed gases cannot be removed by heating at ordinary pressures; Erdmann & Marchand (*J. pr.* 23, 169) found 2 p.c. H and 5 p.c. O in sugar-charcoal which had been heated nearly to whiteness for 3 hours. According to Porcher (*C. N.* 44, 203) amorphous C free from H, O, and N is obtained by passing CCl<sub>4</sub> vapour over hot pure Na in a hard glass tube, and then heating the C obtained to a little under the temperature at which burning begins. A very hard kind of amorphous carbon is formed by placing wood (box, ash, elder, lilac, or oak), or flax, hemp, cotton, paper, or silk, in a porcelain tube, driving out all air by CS<sub>2</sub> vapour and then gradually heating to redness for an hour (Sidot, *C. R.* 70, 605). The harder the wood and the higher the temperature to which it is heated, the harder and denser is the carbon produced. Various materials consisting mainly of carbon are prepared for industrial use; charcoal, by partially burning piles of wood covered with turf or earth, or by the dry distillation of wood; coke, by heating coal in iron retorts arranged so that the liquid and gaseous products may be separated from the residual carbonaceous matter; lamp black, by partially burning tallow, turpentine, &c., and condensing the soot on cold surfaces; animal char (which however contains only about 10-20 p.c. C) by heating bones in closed vessels.

**Properties.**—Unchanged by action of acids; has not been melted or vaporised.

**Diamond** is a colourless, transparent, very refractive and dispersive, crystalline, solid; some diamonds are coloured yellow, brown, blue, or black. Diamond is the hardest substance known, but rather brittle; very bad conductor of electricity and heat. C.E. small, especially at low temperatures, at -42° = 0°. Unchanged by heating out of contact with air to 1300°-1400°; but placed between the carbon poles of a powerful battery it glows brilliantly, swells up, splits, and after cooling the surface resembles coke from bituminous coal (*comp. Rose*, *P.* 168, 497; *v. Schrötter*, *Sitz. W.* [2] 63, 462; *Morre*, *C. R.* 70, 990; *Jacquelin*, *A.* 64, 256; *Gassiot*, *Ph. C.* 1850, 893; *Baumhauer*, *Ar. N.* 8, 1). Unchanged when heated to whiteness in water-vapour (*Baumhauer*, *l.c.*). Strongly heated in a stream of O, diamond is completely burnt to CO<sub>2</sub>; it may also be burnt by heating with molten KNO<sub>3</sub>; or, very slowly, by powdering finely and heating with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, H<sub>2</sub>SO<sub>4</sub>, and a little H<sub>2</sub>O (*Rogers*, *J. pr.* 50, 411).

**Graphite** occurs native both crystalline (*foliated*) and amorphous; it forms a grey, metal-like, hard, opaque, solid; fair conductor of electricity, especially after purification by KClO<sub>3</sub>, &c. (*v. supra*); fair conductor of heat; is not changed by heating out of contact with air; burns in O to CO<sub>2</sub> at a high temperature, but more slowly than diamond; burnt to CO<sub>2</sub> more easily than diamond, by molten KNO<sub>3</sub>, or by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub>; also by heating with various metallic oxides. When graphite is heated with KClO<sub>3</sub> and HNO<sub>3</sub> a compound of

C, H, and O is formed, called by *Brodie* *graphitic acid* (probably C<sub>11</sub>H<sub>2</sub>O<sub>5</sub>); this body is not obtained from diamond or amorphous carbon (*v. Reactions*, No. 13).

The graphite-like form of coke which is formed in the upper parts of the retorts in which coal is heated for gas-making, or is obtained by passing hydrocarbon vapours through red-hot porcelain or iron tubes, is an extremely hard, metal-like, lustrous, sonorous solid; S.G. (2.356) nearly same as that of graphite; it is a good conductor of electricity and a fair conductor of heat; burns with difficulty; it contains no H, and leaves only from 2 to 3 p.c. ash (*Marchand & Meyer*).

**Amorphous carbon** (sugar-charcoal; lamp-black) is a dense, black, powder; it is extremely slowly acted on by any reagents, even energetic oxidisers; non-conductor of electricity. The harder forms of amorphous carbon, obtained by calcining hard woods at high temperatures out of contact with air, somewhat resemble graphite in appearance, they are more or less lustrous, conduct electricity fairly well, and burn slowly when heated in air or O. Ordinary amorphous C, or ordinary wood charcoal, absorbs large volumes of gases: *Saussure* (*G. A.* 47, 113) gives the following volumes absorbed by 1 vol. box-charcoal at 12° and 724 mm.: NH<sub>3</sub> 90, HCl 85, SO<sub>2</sub> 65, H<sub>2</sub>S 55, N<sub>2</sub>O 40, CO<sub>2</sub> 35, CO 9.4, C<sub>2</sub>H<sub>4</sub> 35, O 9.2, N 7.5, H 1.75. *Hunter* (*P. M.* [4] 29, 116; *C. J.* [2] 3, 285; 5, 160; 6, 186; 8, 73; 9, 76; 10, 649) gives these numbers for 1 volume cocoa-nut charcoal at 0° and 760 mm.: NH<sub>3</sub> 171.7, CN 107.5, NO 80.3, CH<sub>4</sub>Cl 70.4, (CH<sub>3</sub>)<sub>2</sub>O 76.2, C<sub>2</sub>H<sub>6</sub> 74.7, N<sub>2</sub>O 70.5, PH<sub>3</sub> 69.1, CO<sub>2</sub> 67.7, CO 21.2, O 17.9. According to *Angus Smith* (*Pr.* 28, 322) absorption of gaseous charcoal takes place in definite volumes; thus if the vol. of H absorbed under definite conditions is 1, the vol. of O = 8, CO = 6, CO<sub>2</sub> = 2, N = 4.66. Chemical reactions sometimes occurs between gases absorbed by charcoal; thus, HCl is produced by leading H over charcoal which has absorbed Cl, and SO<sub>2</sub>Cl<sub>2</sub> by leading SO<sub>2</sub> over charcoal under the same conditions. The absorbed gases are removed *in vacuo*. Recently heated porous wood charcoal removes many colouring matters, e.g. indigo, from solutions; it also removes fusel oil from weak alcohol, alkaloids from aqueous solutions, many metallic salts from solutions, &c.; in some cases chemical change is produced, e.g. CuSO<sub>4</sub> aq and AgNO<sub>3</sub> aq are reduced with pps. of Cu and Ag (*Monde*, *J. pr.* 67, 255; *v. also* *Graham & Hofmann*, *A.* 83, 89; *Graham*, *P.* 19, 139; *Weppen*, *A.* 55, 241; 53, 351; *Favre*, *A. Ch.* [5] 1, 209; *Guthrie & Harms*, *Ar. Ph.* 69, 121; *Stenhouse*, *A.* 90<sup>1</sup>, 186).

**Specific heat of carbon.**—The following numbers summarise the chief determinations exclusive of those of *Weber*: the temperature-interval is about 35°-55°.—

**Diamond:** 143 *Bettendorff & Wüllner* (*P.* 133, 293); 147 *Regnault* (*A. Ch.* [3] 1, 202); 386 [20°-1,000°] *Dewar* (*P. M.* [4] 44, 461).

**Gas carbon:** 165 *Kopp* (*A.* 126, 362; *Supplb.* 3, 1, 289); 186 *B. & W.* (*l.c.*); 197 *R.* (*l.c.*); 32 [20°-1,000°] *D.* (*l.c.*).

**Graphite:** 174 *Kopp* (*l.c.*); 188 *B. & W.* (*l.c.*); 201 *B.* (*l.c.*).

**Wood charcoal: 241 R. (Lp.).**

In 1874 Weber made careful determinations of the S.H. of the different forms of carbon at different temperatures; he used (1) diamond, (2) native graphite, (3) porous wood charcoal in a slender filament strongly heated in dry Cl and sealed at once in a glass tube. His chief results were as follows (v. *P.M.* [4] 49, 161 a. 276):—

**Diamond.**

Temp.	-50°	+10°	65°	250°	606°	985°
S.H.	·0635	·1128	·1765	·3026	·4408	·4529

**Graphite.**

Temp.	-50°	+10°	61°	201°	250°	641°	978°
S.H.	·1138	·1604	·199	·2966	·325	·4454	·467

**Wood Charcoal.**

Temp.	0°	-23°	0°	-99°	0°	-223°
S.H.	·1653	·1935	·1935	·2385	·2385	·2385

These numbers show that the S.H. increases as temp. increases, but that the rate of this increase is much smaller at high than at low temperatures. From 600° onwards the S.H. of diamond is the same as that of graphite; as the values for wood charcoal are nearly the same as those for graphite for the same temperature-intervals, the conclusions may fairly be drawn that at temperatures above 600° the different forms of carbon have all the same S.H., and that at lower temperatures there are two values for the S.H., one belonging to graphite and amorphous C, the other to diamond.

**Allotropy of carbon.** Carbon exhibits allotropic changes in a marked way; diamond may be, superficially at any rate, changed to graphite; amorphous C may also be changed to graphite; each of the three varieties is characterised by special properties. The S.G. of each is characteristic. The heats of combustion (v. *supra*) are different. The S.H.s are not the same; but Weber's results tend to show that, as regards S.H., there is but one form of C existing at temperatures above 600°. Amorphous C remained unchanged when subjected to a pressure of 6,000–7,000 atmos. (Spring, *A. Ch.* [5] 22, 170). The three forms are clearly distinguished, chemically, by their reactions with  $\text{KClO}_3$  and  $\text{HNO}_3$  (v. *Reactions*, No. 9).

**Atomic weight.**—Determined (1) by burning diamond in O and weighing the  $\text{CO}_2$  produced (Dumas & Stas, *A. Ch.* [3] 1, 5; Erdmann & Marchand, *J. pr.* 23, 159; Roscoe, *A. Ch.* [5] 26, 136; Friedel, *Bl.* [2] 41, 100) (2) by heating silver acetate and weighing the Ag (Marignac, *A.* 59, 287); (3) by heating Ag salts (oxalate and acetate) and weighing the Ag and  $\text{CO}_2$  formed (Mauméné, *A. Ch.* [3] 18, 41). The mean of all the (closely agreeing) results is 11·97 (O=15·90).

**Chemical properties.**—The atom of C is tetravalent in gaseous molecules ( $\text{CH}_4$ ,  $\text{CCl}_4$ ,  $\text{CBr}_4$ , &c.). The atomicity of the molecule of C is unknown, as the element has not been gasified; certain considerations, e.g. the increase in S.H. as temperature increases, and perhaps the character of the spectrum, seem to indicate that the molecule of C is probably composed of several atoms.

Carbon is distinctly a non-metallic element; it does not replace the H of acids to form salts; it forms stable, but easily gasified, compounds

with the halogens; its oxides, and also the sulphide  $\text{CS}_2$ , are distinctly acid in their reactions; it exhibits allotropy in a most decided way; the spectrum of C is very complex; yet in some of the physical properties of graphite and dense amorphous carbon, this element approaches the metals (v. *supra*). Carbon stands at the beginning of Group IV. In the periodic classification of the elements; the other members of this group, except Si, are more metallic than non-metallic; C shows closer relations to Si, the first odd-series member of the group, than to any other element in the group (v. *Carbon group or elements*). Both elements are remarkable for the great number of compounds which they form with H, O, and N. Most of the elements of Group IV, except C, form characteristic compounds with F, or double compounds with F and other elements.

**Reactions.**—1. Unchanged by action of acids.

2. Heat, in absence of air, produces no change (*comp. Properties of Diamond*).—3. When strongly heated in excess of oxygen,  $\text{CO}_2$  is formed: the combination is much retarded if the C and O are carefully dried (Baker, *C. J.* 47, 349).—4. Heated with sulphuric acid and potassium dichromate C is slowly burnt to  $\text{CO}_2$ .

5. Oxidised to  $\text{CO}_2$  by heating with molten nitrate or chlorate of potassium.—6. Reacts with sulphur vapour at high temperatures to form  $\text{CS}_2$ .—7. Combines with hydrogen to form  $\text{C}_2\text{H}_2$ ;

by passing electric sparks between C poles in atmosphere of H.—8. Combines indirectly with nitrogen to form cyanogen.—9. Graphite is oxidised by potassium chlorate and nitric acid to graphitic acid ( $\text{C}_6\text{H}_5\text{O}_5$  or  $\text{C}_6\text{H}_4\text{O}_5$ ). Brodie (T. 1859, 249) heated an intimate mixture of 1 part purified and very finely divided graphite and 3 parts  $\text{KClO}_3$ , with enough very conc.  $\text{HNO}_3\text{Aq}$  to bring all into solution, at 60° for 3–4 days, until yellow vapour ceased to come off; the contents of the retort were then poured into much water; the insoluble matter was thoroughly washed by decantation, dried on a water-bath, and again oxidised by  $\text{KClO}_3$  and  $\text{HNO}_3\text{Aq}$ , as before. These operations were repeated (usually 4 times) until no further change was produced, and the insoluble matter formed a clear-yellow solid. Analysis of this yellow solid, dried at 100°, gave the formula  $\text{C}_6\text{H}_5\text{O}_5$ . This body—called graphitic acid by Brodie—forms small, transparent, lustrous, yellow plates; it is slightly soluble in water; insoluble in water containing acids or salts; turns blue-tintus slightly red; shaken with solutions of alkaline bases it appears to form insoluble salts, but the composition of these is very uncertain; when heated it burns explosively, leaving a fine, black residue; it is easily decomposed by reducing agents such as  $(\text{NH}_4)\text{HS}$ ,  $\text{SnCl}_2$ ,  $\text{HIAq}$ , &c. (v. *infra*). Brodie supposed this body to be a compound of a hypothetical element which he called graphon, and to which he gave the atomic weight 33; he formulated graphitic acid as  $\text{Gr}_2\text{H}_5\text{O}_5$ , and regarded it as the carbon analogue of a silicic acid  $\text{Si}_2\text{H}_5\text{O}_5$ , obtained by Wöhler from graphitoid silicon. Gottschalk (*J. pr.* 95, 321) placed a very intimate mixture of 1 part (50 grms.) purified, very finely divided graphite with 3 parts  $\text{KClO}_3$ , in a large flask surrounded by ice-cold water, and, very

slowly added enough  $\text{HNO}_3$  aq. S.G. 1.525, to completely moisten the whole; he then digested at  $50^\circ$  to  $60^\circ$ , and then at  $60^\circ$  to  $70^\circ$ , for 25–30 hours; he poured off the greater part of the acid and dissolved  $\text{KNO}_3$ , washed with hot water by decantation, dried *in vacuo* and then at  $100^\circ$ ; he repeated this treatment 5 or 6 times; finally he washed the residue with  $\text{HNO}_3$  aq. S.G. 1.28, removed the acid by pressing between paper and then by washing with alcohol, washed with ether to remove alcohol, pressed again, and dried on the water-bath in the dark. Gottschalk's analyses lead to the formula  $\text{C}_{11}\text{H}_2\text{O}_6$  for graphitic acid; he describes a salt,  $\text{C}_{11}\text{H}_2\text{O}_6\text{K}_2$ , obtained by treating with conc.  $\text{KOH}$  aq. and washing with cold water.

The action of  $\text{KClO}_3$  and  $\text{HNO}_3$  on graphite has also been investigated by Stingl (B. 6, 391), and by Berthelot (A. Ch. [4] 19, 399). Berthelot calls the compound produced as described *graphitic oxide*, he says it does not react as an acid; he calls the carbon-like mass left on heating graphitic oxide *pyrographitic oxide*; the body is completely dissolved by heating with  $\text{KClO}_3$  and  $\text{HNO}_3$ . The porous, amorphous, insoluble body obtained by heating 1 part graphitic oxide with 20 parts  $\text{HCl}$  aq. S.G. 2.0 to  $280^\circ$ , Berthelot calls *hydrographitic oxide*; this body is not explosively decomposed by heating, treated with  $\text{KClO}_3$  and  $\text{HNO}_3$ , it yields graphitic oxide. There appear to be differences between the *graphitic acids* obtained from different kinds of graphite. Berthelot distinguishes the three allotropic forms of carbon by their reactions with  $\text{KClO}_3$  and conc.  $\text{HNO}_3$ ; amorphous carbon is oxidized to brown humus-like bodies, which dissolve in water; graphite forms graphitic acid; diamond is unchanged. — 10. Both graphite and amorphous carbon are said to yield mellitic acid  $\text{C}_6(\text{CO}_2\text{H})_6$  by the action of  $\text{K}_2\text{Mn}_2\text{O}_8$  in  $\text{KOH}$  aq. (Schulze, B. 4, 802). — 11. Carbon combines with many metals when strongly heated with them, e.g. with Fe, Ni, Co, &c.; none of these carbides has been isolated as a pure compound (v. CARRIDES).

**Carbon, halogen compounds of.** Carbon does not combine directly with the halogens. These compounds are represented by the formulæ  $\text{CX}_4$ ,  $\text{C}_2\text{X}_6$ , and  $\text{C}_3\text{X}_8$ , where  $\text{X} = \text{Br}$  or  $\text{Cl}$ ; when  $\text{X} = \text{I}$  only  $\text{CX}_4$  is known: no fluoride of C has been isolated. The chlorides have been gasified and V.D. of each determined; the formulæ are therefore molecular. The bromides decompose, partially or wholly, when heated: the formulæ are probably molecular. The iodides are easily separated by heat into C and I. The methods of preparation, and reactions, of the chlorides and bromides are very similar.  $[\text{C}, \text{Cl}] = 21.030$ ;  $[\text{C}, \text{Br}] = -1.150$  (at const. press. Thomsen). Besides these compounds, several bromochlorides of carbon exist:  $\text{CBr}_2\text{Cl}_2$ ; two isomeric  $\text{C}_2\text{Br}_2\text{Cl}_2$ ,  $\text{C}_2\text{Br}_3\text{Cl}$ ,  $\text{C}_2\text{Br}_2\text{Cl}_2$ ,  $\text{C}_2\text{Br}_3\text{Cl}$ ,  $\text{C}_2\text{Br}_2\text{Cl}_2$ . [For more details of the halogen compounds of carbon v. the *halogen derivatives of ETHANE, ETHYLENE, and METHANE.*]

**CARBON BROMIDES.** *Carbon dibromide*  $\text{CBr}_2$  (*Tetrabromethylene*). White crystals; M.P.  $53^\circ$ ; produced by heating  $\text{CBr}_4$ , or better, by reducing  $\text{CBr}_4$  with Zn and  $\text{H}_2\text{SO}_4$  aq.; also by reacting with Br on alcohol or ether, adding  $\text{KOH}$  aq. to remove  $\text{HBr}$ , and distilling; or by

treating  $\text{C}_2\text{H}_5\text{Br}$  with alcoholic  $\text{KOH}$  (Lennox, C. J. 14, 209). Decomposed by hot Zn, Cu, Fe, ZnO,  $\text{CuO}$ , &c., giving metallic bromide and CO or  $\text{CO}_2$  (Lewig, A. 8, 292).

*Carbon tribromide*  $\text{CBr}_3$  (*Hexabromide Tetrabromethylene dibromide*). Hard, rectangular prisms, easily soluble in  $\text{CS}_2$ , insoluble in alcohol or ether; decomposed to  $\text{C}_2\text{Br}_4$  and  $\text{Br}_2$  at  $200^\circ$ . Produced by brominating  $\text{C}_2\text{H}_5\text{Br}$ , and by heating  $\text{C}_2\text{H}_5\text{Br}$  with Br and  $\text{H}_2\text{O}$  to  $170^\circ$ – $180^\circ$  (Reboul, A. 124, 271).

*Carbon tetrabromide*  $\text{CBr}_4$  (*Tetrabromo-methane*). White lustrous tables; S.G. 3.42; M.P.  $91^\circ$ . B.P.  $189.5^\circ$  (at 760 mm.) with partial decomposition. Insol. in water, very sol. in alcohol, ether, or  $\text{CHCl}_3$ . Partially decomposed with liberation of Br, at  $200^\circ$ ; with alcohol at  $100^\circ$  gives  $\text{HBr}$ ,  $\text{CHBr}_3$ , and  $\text{CH}_2\text{Br}_2$ ; with alcoholic  $\text{NH}_3$  at  $100^\circ$  gives  $\text{CHBr}_3$  and a little guanidine. Formed by the reaction between (1) Br, in presence of I or  $\text{SbBr}_3$ , and  $\text{CHBr}_3$ , or  $\text{CS}_2$  or  $\text{CBr}_2(\text{NO}_2)$ ; (2) Br, in presence of I, and  $\text{CHCl}_3$ . Best prepared by heating 1 part  $\text{CS}_2$  with  $1\frac{1}{2}$  parts I and 7 parts Br to  $150^\circ$ – $160^\circ$  for 48 hours in a closed tube, shaking contents of tube with  $\text{NaOH}$  aq. distilling in steam, pressing between paper, and crystallising from alcohol (Bolas a. Groves, C. J. [2] 8, 161; 9, 773).

**CARBON CHLORIDES.** *Carbon dichloride*  $\text{CCl}_2$  (*Tetrachlorethylene*). Colourless liquid; ethereal odour; S.G. at  $10^\circ$  1.62 (R.), 1.612 (G.); S.G. at  $0^\circ$  1.6595 (B.). B.P.  $122^\circ$  (R.),  $116.7^\circ$  (G.),  $121^\circ$  (B.). V.D. 5.82. Easily combines with Cl in sunlight forming  $\text{CCl}_4$ . Prepared by reducing  $\text{CCl}_4$ ;  $\text{CCl}_4$  is placed in a flask with water and Zn,  $\text{H}_2\text{SO}_4$  aq. is added from time to time, the flask being kept cold and frequently shaken; the  $\text{CCl}_2$  is distilled over in steam, dried, and fractionated (Faraday, T. 1821. 47; Regnault, A. Ch. 2, 377; Geuther, A. 107, 212; Bourgois, B. 23, 344).

*Carbon trichloride*  $\text{CCl}_3$  (*Tetrachlorethylene dichloride. Carbon hexachloride*). Hard, colourless, rhombic prisms; S.G. 2.0. M.P.  $187^\circ$  and B.P. the same (Stadel a. Hahn, B. 9, 1735). V.D. 8.15. Insol. in  $\text{H}_2\text{O}$ , sol. in alcohol or ether. Easily reduced, e.g. by Zn and  $\text{H}_2\text{SO}_4$  aq. or by alcoholic  $\text{KHS}$ , to  $\text{CCl}_2$ ; with  $\text{KOH}$  aq. at  $200^\circ$  gives  $\text{KCl}$ ,  $\text{H}_2\text{O}$ , and  $\text{K}_2\text{C}_2\text{O}_4$ . Prepared by leading Cl into boiling  $\text{C}_2\text{H}_5\text{Cl}$  till saturated, cooling by ice, pressing between paper, dissolving in alcohol, ppg. by  $\text{H}_2\text{O}$ , pressing, and crystallising from alcohol (Faraday, T. 1821. 47; Regnault, A. Ch. 69, 165; 71, 371; Liebig, A. 1, 219; Geuther, A. 60, 247; Berthelot, A. 109, 118).

*Carbon tetrachloride*  $\text{CCl}_4$  (*Tetrachloro-methane*). Colourless liquid, with ethereal odour; S.G. at  $10^\circ$  1.63195; B.P.  $76.74^\circ$  (Thorpe, C. J. 37, 199). V.D. 5.24. Prepared by leading dry Cl into boiling  $\text{CHCl}_3$  containing a little  $\text{SbCl}_3$  or  $\text{I}_2$ , in a large flask with inverted condenser, removing excess of Cl by shaking with  $\text{Hg}$ , and fractionating. Also by passing  $\text{CS}_2$  and Cl through a hot porcelain tube (Kolbe, A. 45, 41; 54, 146). Unchanged by  $\text{KOH}$  aq.; with alcoholic  $\text{KOH}$  slowly gives  $\text{KCl}$ ,  $\text{K}_2\text{CO}_3$ , and  $\text{H}_2\text{O}$ ; passed through a hot tube gives  $\text{CCl}_2$ ,  $\text{C}_2\text{Cl}_4$ , and C; heated with  $\text{SO}_2$  gives  $\text{COCl}_2$  and  $\text{S}_2\text{O}_2\text{Cl}_2$ ; with  $\text{P}_2\text{O}_5$  gives  $\text{POCl}_3$  and  $\text{COCl}_2$ .

(Regnault, *A. Ch.* 71, 877; Dumas, *A. Ch.* 73, 95).

**CARBON IODINE.**  $\text{CI}_4$ . Dark red octahedra; S.G.  $2^{\circ}$  4.32; sol. in alcohol, ether, or  $\text{CS}_2$ . Decomposed by heat to C and I; boiled with  $\text{H}_2\text{O}$  or dilute  $\text{HIAq}$  gives  $\text{CHI}_3$ . Prepared by mixing equal vols.  $\text{CCl}_4$  and  $\text{CS}_2$  with a saturated solution of  $\text{AlI}_3$  in  $\text{CS}_2$ , then diluting with  $\text{H}_2\text{O}$  out of contact with air. The solution of  $\text{AlI}_3$  is prepared by placing the proper quantities of Al (in small pieces) and I in a stoppered flask and adding 3 times the quantity of  $\text{CS}_2$  (Gustavson *B.* 14, 1705).

**CARBON BROMOCHLORIDES:** *Trichlorobromomethane*  $\text{CCl}_3\text{Br}$ ; *two tetrachlorodibromo-ethanes*  $\text{C}_2\text{Cl}_4\text{Br}_2$ ; *dichlorotetrabromo-ethane*  $\text{C}_2\text{Cl}_2\text{Br}_4$ ; *chloropentabromo-ethane*  $\text{C}_2\text{ClBr}_5$ ; *dichlorodibromopentachloro-ethane*  $\text{C}_2\text{Cl}_2\text{Br}_3$ ; *chlorotribromopentachloro-ethane*  $\text{C}_2\text{ClBr}_4$  (v. these compounds under METHANE, ETHANE, and ETHYLENE).

**Carbon, hydrate of (?)** By treating pig-iron with (1)  $\text{CuSO}_4\text{aq}$ , (2)  $\text{FeCl}_3\text{aq}$  containing  $\text{HCl}$ , a brownish-black substance remains, containing, according to Schützenberger a. Bourgeois (*C. R.* 80, 911) carbon and water in the ratio  $11\text{C} : 3\text{H}_2\text{O}$ . Besides the C and  $\text{H}_2\text{O}$ , the substance gives about 10 p.c. ash. It loses  $3\text{H}_2\text{O}$  at  $250^{\circ}$ .

**Carbon nitride = CYANOGEN** (*q. v.*).

**Carbon, oxides of.** Two oxides certainly exist,  $\text{CO}$  and  $\text{CO}_2$ ; these formulae are molecular; each bears the relation of anhydride to an acid,  $\text{CO}$  is formic anhydride (the acid is  $\text{H}_2\text{CO}_3$ ),  $\text{CO}_2$  is carbonic anhydride (the acid is  $\text{H}_2\text{CO}_3$ ) (*v. infra*). Both oxides can be obtained by direct combination of O with C; either can be produced from the other, by combining with O or with C, respectively. Both are stable gases;  $\text{CO}$  is an energetic reducer;  $\text{CO}_2$  in a few cases acts as an oxidiser. Brodie (*Tr.* 21, 215) and Berthelot (*B.* [2] 21, 102) have described bodies, produced by the induced electric discharge on  $\text{CO}$ , as oxides of C. Brodie noticed a gradual diminution in vol. of the  $\text{CO}$  and the formation of a red-brown film on the glass tube; the solid was soluble in water giving a markedly acid solution; its composition appeared to differ in different experiments; Brodie gives the formula  $\text{C}_3\text{O}_4$  and  $\text{C}_3\text{O}_5$ . Berthelot got brown, amorphous, humus-like bodies which dissolved in water with acid reactions, gave brown pps. with  $\text{AgNO}_3\text{aq}$ ,  $\text{BaOaq}$ , and  $\text{Pb}_2\text{NO}_3\text{aq}$ ; at  $300^{\circ}$ – $400^{\circ}$   $\text{CO}$  and  $\text{CO}_2$  (equal vols.) were evolved, and another dark body remained, to which B. gave the composition  $\text{C}_3\text{O}_4$ . B. also (*A. Ch.* [5] 17, 142) states that by the action of electric sparks on pure  $\text{CO}$ , a gas was produced which reacted violently with Hg and oxidisable bodies.

**CARBON MONOXIDE.**  $\text{CO}$ . (*Carbonic oxide*; more properly, although rarely, *carbonous oxide*; *formic anhydride*.) Mol. w. 27.93. S.G. .9678 (*air* = 1). V.D. 14.  $d_4^{20}$  (c.  $-18^{\circ}$ ) (Wroblewski, *C. R.* 98, 982). S.H. p. 2346. S.H.  $v$ . 16844 (E. Wiedemann, *P.* 157, 1).  $d_4^{20}$  .003667 (Regnault). S. ( $6^{\circ}$ ) .0287; ( $9^{\circ}$ ) .0269; ( $13^{\circ}$ ) .02315 (Bunsen). S. alcohol ( $2^{\circ}$ ) .20356; ( $13^{\circ}$ ) .20416; ( $16^{\circ}$ ) .20566; ( $24^{\circ}$ ) .20452 (Bunsen).  $\mu_0 = 1.000301$ ;  $\mu_D = 1.000350$ ;  $\mu_n = 1.000891$  (Croullebois, *A. Ch.* [4] 20, 136).  $[\text{CO}, \text{O}] = 67,960$  at const. press., and 67,670 at const. vol.;  $[\text{C}, \text{O}] = 29,000$ , and 29,290, respec-

Vol. I.

tively (Thomsen). Does not exactly obey Boyle's law;  $\frac{PV}{P_1V_1} = 1.00293$  (Regnault, *Acad.* 1862. 26,

229). Liquefied by cooling to  $-136^{\circ}$  at pressure of 200–300 atmos. and then decreasing pressure, not too quickly, to not less than 50 atmos. (Wroblewski a. Olszewski, *A. Ch.* [6] 1, 112; v. also Natter, *W. A. B.* 12, 199; and Cailletet, *C. R.* 85, 1213 a. 1217, and *A. Ch.* [5] 15, 132). First obtained in 1776, by Lavoisier, by heating C with  $\text{ZnO}$ ; obtained by Priestly, in 1796, by heating charcoal with iron oxide, but supposed by him to be H; proved by Cruikshank not to be a hydrocarbon; true composition determined by Clement and Desormes.

**Occurrence.** In the gases from burning coal or charcoal; from the partial combustion or putrefaction of organic matter; or from the reduction of metallic oxides by charcoal, e.g. in the blast-furnace (Bareswil, *J. Ph.* [3] 25, 172; Bunsen, *P.* 46, 193; 50, 81). During the oxidation of gallic and tannic acids by exposure to air in alkaline solutions (Boussingault, *A. Ch.* [3] 66, 295; Calvert, *C. R.* 57, 873). In pig-iron and steel according to Troost a. Hautefeuille, also Parry (*J.* 1873. 997; 1874. 1083).

**Formation.**—1. By passing steam over excess of red-hot C; the product may contain about  $28\frac{1}{2}$  p.c.  $\text{CO}$ ,  $56\frac{1}{2}$  p.c. H,  $14\frac{1}{2}$  p.c.  $\text{CO}_2$ , and traces of  $\text{CHI}$ , (v. Naumann a. Pistor, *B.* 18, 164). 2. By passing a slow current of  $\text{CO}$  over red-hot C, and washing the gases through  $\text{KOHaq}$  and soda-lime.—3. By heating  $\text{CO}_2$  with those metallic oxides which do not readily part with O, e.g.  $\text{ZnO}$ ,  $\text{PbO}$ ,  $\text{Fe}_2\text{O}_3$ , oxides which readily give up O yield but little  $\text{CO}$ , as it is again oxidised to  $\text{CO}_2$ .—4. By passing  $\text{CO}_2$  over red-hot Cu, or over hot Zn-dust (Noack, *B.* 16, 75).—5. By heating  $\text{CO}_2$  to  $1300^{\circ}$  (Deville, *C. R.* 59, 873).—6. By electric sparks through  $\text{CO}_2$  (Buff a. Hofmann, *A. Ch.* 140).—7. By heating powdered  $\text{CaCO}_3$  or  $\text{K}_2\text{CO}_3$  with one-sixth its weight of powdered charcoal;  $\text{Na}_2\text{SO}_4$  heated with C also yields  $\text{CO}$  (with  $\text{Na}_2\text{S}$ ).—8. In very small quantities (with  $\text{COS}$ ) by passing  $\text{CO}_2$  and S vapour through a red-hot tube (Berthelot, *A. Ch.* [5] 30, 547).—9. By heating dry  $\text{H}_2\text{C}_2\text{O}_4$ , or by reaction between  $\text{H}_2\text{C}_2\text{O}_4$  or an oxalate and hot conc.  $\text{H}_2\text{SO}_4$ .—10. By heating  $\text{H}_2\text{CO}_3\text{H}$ , or a formate, with conc.  $\text{H}_2\text{SO}_4$ .

**Preparation.**—1. One pt. dry powdered  $\text{K}_2\text{Fe}(\text{CN})_6$  is heated in a capacious vessel, with 8–10 pts. conc.  $\text{H}_2\text{SO}_4$ ; as soon as frothing begins the lamp is lowered to a small flame; the gas is passed through milk of lime and  $\text{KOHaq}$  to remove  $\text{CO}$ , and the  $\text{SO}_2$  formed in the process;  $\text{SO}_2$  is evolved only in the earlier stages of the reaction (Grimm a. Ramdohr, *A.* 98, 127). 15 g.  $\text{K}_2\text{Fe}(\text{CN})_6$  yield about 4 litres  $\text{CO}$ :  

$$\text{K}_2\text{Fe}(\text{CN})_6 + 6\text{H}_2\text{SO}_4 + 6\text{H}_2\text{O} = 6\text{CO} + 2\text{K}_2\text{SO}_4 + 3(\text{NH}_4)_2\text{SO}_4 + \text{FeSO}_4 \text{ (Fownes).}$$
 2. Dry  $\text{CaC}_2\text{O}_4$ , or  $\text{BaC}_2\text{O}_4$ , is mixed with about  $\frac{1}{2}$  pt. dry  $\text{CaO.H}_2\text{O}$ , and the mixture is strongly heated in a hard glass flask; the gas is passed through milk of lime, and is then dried:— $\text{CaC}_2\text{O}_4$  gives  $\text{CaCO}_3 + \text{CO}$ ; the  $\text{CaH}_2\text{O}$  absorbs any  $\text{CO}_2$  formed.—3. According to Cherrier (*C. R.* 69, 138) pure  $\text{CO}$  may be prepared by passing the gases produced by heating  $\text{H}_2\text{C}_2\text{O}_4$  with  $\text{H}_2\text{SO}_4$  through a red-hot tube filled with

Y Y

charcoal, and then through a mixture of  $\text{CaOaq}$  and  $\text{KOHaq}$ .

**Properties.**—A colourless, tasteless, slightly odorous gas; liquefied at low temperature and great pressure (*v. supra*). CO is combustible but a non-supporter of combustion: the temperature of the flame of CO in air is about  $1400^\circ$  (Valerius, J. 1874, 58). Absorbed by C, and by several metals, e.g. K, Ag, Au; quickly absorbed by  $\text{Cu}_2\text{Cl}_2$  in a little  $\text{HClaq}$  (*v. infra*); decomposed at very high temperature to C and  $\text{CO}_2$ ; decomposed when moist by induction-sparks; CO is an energetic reducer; it combines with moist KOH (or NaOH) to form K formate; combines directly with Cl and Br in sunlight. CO is extremely poisonous; it removes O from the blood and combines with the hæmoglobin. CO may be detected in the blood by observing the absorption-spectrum; this is almost identical with that of oxygenated blood, and is characterised by two bands between D and E; on adding a little ammonium sulphide these bands disappear in the case of oxygenated blood, and the spectrum shows one band midway between D and E; if the blood contains CO the two bands remain unchanged for several days (Vogel, B. 11, 235; Hoppe-Seyler, *Pr.* 3, 439).

**Reactions.**—1. *Electric sparks* cause a partial decomposition to  $\text{CO}_2$  and C; if the  $\text{CO}_2$  is removed the change proceeds (Berthelot, A. Ch. [5] 30, 547). According to Berthelot (Bl. [2] 21, 102; A. Ch. [5] 17, 142) CO is decomposed by the *induction-discharge*, with production of  $\text{CO}_2$  and (?)  $\text{C}_2\text{O}_2$  and  $\text{C}_2\text{O}_4$  (*v. ante*; beginning of this art.). According to W. Hoffmann (C. J. 12, 282) the induction-spark does not decompose dry pure CO. Dixon (C. J. 49, 103) found that CO was decomposed (only about  $\frac{1}{2}$  p.c. of the total gas) by sparks from a Leyden jar.—2. *Heated* to about  $1300^\circ$  CO is partially decomposed to C and  $\text{CO}_2$  (Deville, C. R. 59, 873).—3. A mixture of CO with oxygen is burnt to  $\text{CO}_2$  by application of a flame or electric sparks. Dixon (T. 1884, 617) has proved that if both gases are perfectly dry no chemical change occurs when a spark is passed; that a mere trace of steam renders the mixture explosive; that the oxidation of CO by O takes place very slowly if only a very small quantity of steam is present; and that as the quantity of steam is increased the rapidity of the explosion is increased also. The steam acts as a carrier of O to the CO; it is probably reduced, and the H is then again oxidised: the reactions which occur are very probably these (*v. Dixon, C. J. 49, 94*):

Or (Armstrong, C. J. 49, 112) the changes may be represented by the formulae, *before explosion*  $\text{O.H}_2\text{O.CO}$ ; *after explosion*  $\text{OH}_2\text{OCO}$ . Small quantities of gases other than  $\text{H}_2\text{O}$  were tried ( $\text{H}_2\text{S}$ ,  $\text{C}_2\text{H}_4$ ,  $\text{H}_2\text{CO}$ ,  $\text{NH}_3$ ,  $\text{C}_2\text{H}_2$ ,  $\text{HCl}$ ;  $\text{SO}_2$ ,  $\text{CS}_2$ ,  $\text{CO}_2$ ,  $\text{N}_2\text{O}$ ,  $\text{C}_2\text{N}_2$ ,  $\text{CCl}_4$ ); if the gas contained H, explosion occurred; if the gas did not contain H the mixture did not explode.—4. When a mixture of CO and steam is heated to about  $600^\circ$ , a portion of the CO is oxidised to  $\text{CO}_2$ ; the amount of CO oxidised depends on the conditions (*v. Dixon, C. J. 49, 94*; references to other memoirs are given); if the  $\text{CO}_2$  is removed as it is formed the whole of the CO can be

oxidised. L. Meyer's experiments (B. 19, 1099), however, seem to prove that a mixture of dry CO and O can be exploded by a very strong spark is used, and the temperature is thus made very high. The gases must be under considerable pressure; the more dilute the gaseous mixture the more difficult is it to explode it.—5. When sparks from an induction-coil are passed through a mixture of CO and steam,  $\text{CO}_2$ , a little formic acid, and in some cases C, are formed (Dixon, C. J. 49, 94).—6. When to a mixture of dry CO with hydrogen, oxygen in sufficient for complete combustion is added, and the mixture is exploded by the spark,  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are formed; the ratio of  $\text{CO}_2$  to  $\text{H}_2\text{O}$  depends on the shape of the vessel, and the pressure up to a certain limit; above this pressure—the 'critical pressure'—the ratio  $\text{CO}_2:\text{H}_2\text{O}$  is independent of the shape of the vessel. The larger the quantity of O used the lower is the critical pressure. So long as the volume of H is more than twice that of the O the ratio of  $\text{CO} \times \text{H}_2\text{O}:\text{CO}_2 \times \text{H}_2$  remains constant, provided no  $\text{H}_2\text{O}$  can condense, and the pressure is above the critical pressure: when the vol. of H is less than twice that of O the value of the ratio diminishes. The presence of an inert gas, e.g. N, increases the formation of  $\text{CO}_2$  and diminishes that of  $\text{H}_2\text{O}$ , hence it lowers the value of the ratio  $\text{CO} \times \text{H}_2\text{O}:\text{CO}_2 \times \text{H}_2$ . This ratio is called by Dixon the *co-efficient of affinity* of the reaction (*v. Dixon, T. 1884, 617; C. J. 49, 94; Horstmann, B. 12, 64; v. also CHEMICAL CHANGE*).—7. CO is oxidised to  $\text{CO}_2$  (1) by *bichrome and sulphuric acid* (Ludvig, J. 1872, 218); (2) by *platinum charged with hydrogen*, in presence of oxygen and water,  $\text{H}_2\text{O}_2$  being also produced (Traube, B. 15, 2325, 2854; 16, 123; Remsen a. Keiser, B. 17, 83); (3) by *mixing with oxygen and passing over aluminium-black*; (4) by *nitrogen dioxide* [ $\text{NO}_2$ ] (Hasenbach, J. pr. [2] 41); (5) by *heating with most metallic oxides*; (6) by *heating with many oxysalts*, e.g. alkaline sulphates (sulphides produced).—8. Many experiments have been made to determine whether CO is oxidised by contact with moist oxygen in presence of slowly oxidising phosphorus; the balance of evidence seems to show that  $\text{CO}_2$  is not produced (Remsen (and others) Am. S. [3] 11, 316; B. 17, 83; Am. 6, 153; Leeds, B. 12, 1836; C. N. 48, 25; Baumann, B. 16, 2146; 17, 283).—9. CO reacts with moist *potash* or *soda* to form alkali formate (Berthelot, A. Ch. [3] 61, 463); the reaction proceeds most quickly at  $190^\circ$ – $200^\circ$ , and is best accomplished by leading moist CO over soda-lime (Fröhlich a. Geuther, A. 202, 317).—10. With *ferrous oxide* at  $300^\circ$ – $400^\circ$ ,  $\text{CO}_2$  and a little C are formed (Grüner, C. R. 73, 281).—11. CO appears to react with certain *metallic peroxides* to form carbonates, but, according to Wright a. Luff (C. J. 33, 540),  $\text{CO}_2$  is formed by partial reduction of the peroxide and reacts with the lower oxide to produce carbonate.—12. Many of the preceding reactions exhibit CO as a *reducing agent*; it also reduces  $\text{PdCl}_2\text{aq}$  to Pd.—13. When *sodium or potassium is heated to redness* in CO, alkali carbonate and C are formed.

**Combinations.**—1. With *potassium* at about  $80^\circ$  to form the explosive compound KCO (Brodie, C. J. [2] 12, 269), *v. POTASSIUM*.—

2. With *chloride or bromine* in sunlight, to form  $\text{COCl}_2$ , or  $\text{COBr}_2$  (v. CARBON, OXYCHLORIDE, and OXYBROMIDE, &c.).—3. With *sulphur* to form COS (v. CARBON, OXYSULPHIDE, &c.).—4. With *platinic chloride* to form  $\text{C}_2\text{O}_3\text{PtCl}_2$ , and  $\text{C}_2\text{O}_3\text{PtCl}_2$  (Schützenberger, *A. Ch.* [4] 21, 350).—5. CO is absorbed by anhydrous HCN (Böttger, *B.* 10, 1122); by several metals, e.g. Fe, Ag, Au; by carbon.—6. CO does *not* combine with cyanogen, nor does it react with  $\text{Hg}(\text{CN})_2$ .

*Estimation*.—CO in a gaseous mixture is absorbed by  $\text{Cu}_2\text{Cl}_2$  solution. Thomas (*C. N.* 37, 6) prepares the solution by filling a vessel of 120 c.c. capacity  $\frac{3}{4}$  full of Cu turnings, adding 6 g. crystallised  $\text{CuCl}_2$  and 20 c.c. conc.  $\text{HClAq}$ , and shaking until solution of the  $\text{CuCl}_2$  is effected; he then adds 30 c.c. water and shakes briskly for some time, and then adds 30 c.c. water.

CARBON DIOXIDE.  $\text{CO}_2$ . (*Carbonic anhydride*, often called *carbonic acid*.) Mol. w. 44.01. S.G. gas 1.53; S.G. liquid 1.057 at  $-34^\circ$ ; 1.016 at  $-25^\circ$ ; .966 at  $-11.5^\circ$ ; .91 at  $-1.6^\circ$ ; .84 at  $+11^\circ$ ; .726 at  $+22.2^\circ$  (Cailliet a. Mathias, *C. R.* 102, 1202). S.G. solid (hammered) slightly under 1.2 (Landolt, *B.* 17, 309) [ $-65^\circ$ ] (Mitchell); [ $-57^\circ$ ] (Faraday); [ $-78.2^\circ$ ] (Regnault, *A. Ch.* [3] 26, 257). V.D. 22; 22.42 at  $800^\circ$ ; 21.2 at  $1180^\circ$  (Meyer a. Goldschmidt, *B.* 15, 1165). S.H.v. .33 (equal vol. of air = 1), .2169 (equal weight of air = 1) (Regnault, *C. R.* 36, 676, &c.;

v. also Wiedemann, *P.* 157, 21). S.H.p. = 1.29 S.H.v.

to 1.305 (Amagat, Röntgen, *C. R.* 71, 336; 77, 1325). C.E. .0037 (Regnault, Magnus, Joly).

$\frac{PV}{T}$  = 1.00722 (Regnault, *C. R.* 20, 975). At P.V.  $200^\circ$   $\text{CO}_2$  obeys Boyle's law (Amagat, *C. R.* 68, 1170; 73, 183). C.E. liquid  $\text{CO}_2$  very large, 120 c.c. at  $-20^\circ$  become 150 vol. at  $+30^\circ$  (Thilorier, *A. Ch.* 60, 427). Critical temperature =  $30.9^\circ$  (Andrews, *T.* 1869, 575). Vapour-pressure of liquid  $\text{CO}_2$  (Regnault) in atmospheres:  $-25^\circ$ , 17.1;  $-5^\circ$ , 30.9;  $0^\circ$ , 35.4;  $+5^\circ$ , 40.5;  $15^\circ$ , 52.2;  $25^\circ$ , 66;  $35^\circ$ , 82.2;  $45^\circ$ , 100.4. Vapour-pressure of solid  $\text{CO}_2$  (Faraday) in atmos.:  $-57^\circ$ , 5.33;  $-70.5^\circ$ , 2.2;  $-99.4^\circ$ , 1.14. B.P. of solid  $\text{CO}_2$ —i.e. temp. at which vapour-pressure = 760 mm.—is much lower than the M.P.; Regnault (and Pouillet) found  $-78^\circ$  to  $-79^\circ$  (*P.* 77, 107); Thilorier,  $-95^\circ$  to  $-98^\circ$ ; and Faraday, as shown by values for vapour-pressure, under  $-99^\circ$ . By evaporation of solid  $\text{CO}_2$  mixed with ether, temp. is c.  $-100^\circ$ .

S.  $\text{CO}_2$  gas (Bunsen, *A.* 93, 17):

At $0^\circ$	1.7967	At $11^\circ$	1.1416
1	1.7207	12	1.1018

$$4.32955 - .09355t + .00121t^2.$$

$\mu_0 = 1.000395$ ,  $\mu_2 = 1.000156$ ,  $\mu_4 = 1.000496$  (Croulebois, *A. Ch.* [4] 20, 136; v. also Chapuis a. Rivière, *C. R.* 103, 37). H.F.p. [ $\text{C}_2\text{O}_2$ ] = 96,960; [ $\text{CO}_2\text{O}$ ] = 67,960. H.F.v. [ $\text{C}_2\text{O}_2$ ] = 96,960; [ $\text{CO}_2\text{O}$ ] = 67,670. [ $\text{C}_2\text{O}_2\text{Aq}$ ] = 102,840. [ $\text{CO}_2\text{O}_2\text{Aq}$ ] = 73,840. [ $\text{CO}_2\text{Aq}$ ] = 5,880. [ $\text{CO}_2\text{Aq}$ NaOH Aq];  $n=1$  = 11,016;  $n=2$  = 20,184;  $n=4$  = 20,592 (Thomsen).

Carbon dioxide has been known for centuries. The identity of the gases produced during fermentation and by the action of acids on chalk was established by Black. Bergmann recognised the same gas in the atmosphere. Cavendish proved that the same gas was produced by burning charcoal. Lavoisier established the composition of the gas. Faraday liquefied, and Thilorier solidified, carbon dioxide.

*Occurrence*.—In the atmosphere (v. ATMOSPHERE); in mineral waters; issues from the earth in different places; sometimes found liquid in cavities in quartz, &c. Produced by the breathing of animals, by the decay of organic matter, by the combustion of coal, charcoal, &c. In combination as carbonate, of calcium, magnesium, &c., &c.

*Formation*.—1. By burning C in air or O.—2. By oxidation of most C-compounds.—3. By burning  $\text{CO}$ .—4. By reducing many metallic oxides by C.—5. By heating together  $\text{H}_2\text{O}$  and  $\text{CO}$ .—6. By the reaction between red hot C and steam.—7. By the action of steam on  $\text{CaCO}_3$  at red heat.—8. By heating a mixture of  $\text{K}_2\text{Cr}_2\text{O}_7$  with  $\text{Na}_2\text{CO}_3$ .—9. By heating several carbonates. 10. During fermentation. 11. By reaction between acids and carbonates.

*Preparation*.— $\text{CaCO}_3$ ,  $\text{MgCO}_3$  in lumps is treated with dilute  $\text{HClAq}$  at the ordinary temperature; the gas is passed through  $\text{NaHCO}_3\text{Aq}$  (to remove  $\text{HCl}$  which may have passed over), and is then dried by  $\text{CaCl}_2$ . Bunsen recommends the use of finely powdered chalk and conc.  $\text{H}_2\text{SO}_4$ , and addition of a very little water.

Liquid carbon dioxide was obtained by Faraday by decomposing  $(\text{NH}_4)_2\text{CO}_3$  by  $\text{H}_2\text{SO}_4\text{Aq}$  in a limb of closed glass tube bent at an oblique angle. Thilorier (*A. Ch.* 60, 247) decomposes  $\text{NaHCO}_3$  by dilute  $\text{H}_2\text{SO}_4\text{Aq}$  in an iron vessel connected with an iron cylinder in which the  $\text{CO}_2$  is liquefied by its own pressure. Natterer (*J. pr.* 35, 169) compresses  $\text{CO}_2$  by a specially constructed air-pump (v. also Gore, *T.* 1861, 63).

Solid carbon dioxide is obtained by allowing the liquid to escape into a tin vessel; part of the liquid becomes gas and part is solidified. Landolt allows the liquid to evaporate freely into conical woollen bags; he then compresses the solid  $\text{CO}_2$  in conical moulds of hard wood by wooden pistons (*B.* 17, 309).

*Properties*.—A heavy, colourless, gas; incombustible; non-supporter of ordinary combustion, but strongly heated K or Na, or brightly burning Mg, burns in  $\text{CO}_2$ . Absorbed by water, solution colours litmus wine-red and reacts as

a weak acid (*v.* CARBONIC ACID). Absorbed by moist alkalis and alkaline earths forming carbonates; rapidly absorbed by mixture of powdered KOH and hydrated  $\text{Na}_2\text{SO}_4$ . Poisonous, by cutting off supply of O.

Liquid carbon dioxide is a limpid, colourless, refractive, liquid; nonconductor of electricity; not changed by strong induction-sparks; very expansible by heat; C.E. is greater than that of the gas. Insol. in water which swims on the surface; mixes with alcohol, ether, &c. Does not dissolve S or P; dissolves I; no reaction with Na or K (Cailliet, *C. R.* 75, 1271).

Solid carbon dioxide is a white, loose, snow-like, solid; when compressed by hammering in wooden moulds it resembles chalk (Landolt, *B.* 17, 309). Very bad conductor of heat. Evaporates slowly, a specimen prepared by Landolt 53 mm. by 71 mm. diam. took 5 hours to volatilise in the air. Burns, if pressed against the skin.

*Reactions.*—1. Heated to c.  $1300^\circ$  in porcelain tube is partly changed to CO and O (Deville, *C. R.* 56, 729; *v.* also Berthelot, *C. R.* 68, 1035).—2. Partly decomposed by electric sparks; a condition of equilibrium is attained when change of  $\text{CO}_2$  into CO + O equals that of CO and O into  $\text{CO}_2$  (Dixon a. Lowe, *C. J.* 47, 571).—3. Mixed with hydrogen, and heated to bright redness or submitted to induction-sparks,  $\text{H}_2\text{O}$  and CO are formed; if  $\text{H}_2\text{O}$  is removed the whole of the  $\text{CO}_2$  goes to CO (Dixon, *C. J.* 49, 94). According to Dubrunfaut (*C. R.* 74, 125)  $\text{CO}_2$  and H passed over hot pumice give C and  $\text{H}_2\text{O}$ .—4. A mixture of carbon dioxide and sulphur vapour passed through a red-hot tube yield a little COS, CO, and  $\text{SO}_2$  (Berthelot, *Bl.* [2] 40, 362).—5. With sulphuretted hydrogen, passed through red-hot tube, forms CO,  $\text{H}_2\text{O}$  and S (Köhler, *B.* 11, 205).—6. Decomposed by chlorophyll-parts of plants in sunshine.—7. Reduced to CO by heating with carbon, iron or zinc, or with copper which has occluded hydrogen (Tissandier, *C. R.* 74, 531; Schrötter, *W. A. B.* 34, 27).—8. Partly reduced to CO by reaction with ferrous sulphate and a little water, in a closed tube (Horsford, *B.* 6, 1390).—9. Reduced to C by heating strongly with sodium, potassium, or magnesium; alkali carbonates strongly heated with phosphorus or boron give CO, which is reduced to C (Tennant, *Crellis A.* [1793] 1, 158; Pragen-dorff, *J.* 1861, 111; Leeds, *B.* 12, 1834 a. 2131).—10. With moist alkalis, or alkaline earths, forms carbonates.—11. With water probably forms a solution of carbonic acid,  $\text{H}_2\text{CO}_3$  (*v.* CARBONIC ACID).—12. With sodium- or potassium-amalgam at c.  $350^\circ$  gives Na (or K) oxalate (Drechsel, *A.* 146, 141).—13. With sodium  $\text{CO}_2\text{Aq}$  reacts to give Na formate (Kolbé a. Schmitt, *A.* 119, 251).—14. Decomposes moist potassium iodide at high temperature giving HI (Papaasogli, *G.* 1881, 227).

Carbon, oxybromide. The existence of a Br compound of CO analogous to  $\text{COCl}_2$  is doubtful. A mixture of Br vapour with excess of CO is slowly, but not fully, decolourised in sunlight; in contact with KOHAq this gas produces KBr and  $\text{K}_2\text{CO}_3$  (Schiel, *A. Suppl.* 2, 311). Emmerling a. Lengyel could not obtain a trace of any compound of C, Br, and O, by the reaction between COS and Br at a high temperature (*B.* 2, 547). By the reaction between

$\text{H}_2\text{SO}_4$  (50 parts),  $\text{K}_2\text{Cr}_2\text{O}_7$  (20-25 parts), and  $\text{CHBr}_3$  (5-10 parts), Emmerling (*B.* 13, 874) obtained a small quantity of a liquid, which he slowly distilled through Sb, to remove Br; he thus obtained a colourless heavy liquid, smelling like  $\text{COCl}_2$ . The B.P. rose from  $12^\circ$  to  $30^\circ$ ; analyses seemed to show that the liquid was a mixture of  $\text{COCl}_2$  and C oxybromide.

Carbon, oxychloride of.  $\text{COCl}_2$ . (Carbonyl chloride. Phosgenegas. Chloro-carbonic acid) Mol. w. 98.67. ( $8.2^\circ$  at 756 mm.). S.G.  $\frac{4}{3}$  (liquid) 1.432;  $\frac{18.6^\circ}{4}$  1.392 (Emmerling a. Lengyel, *A. Suppl.* 7, 101). V.D. 50.6 (E. a. L.).  $[\text{C}_2\text{O}_2\text{Cl}_2] = 54,850$  at constant volume; 55,140 at constant pressure (Thomsen). First prepared by J. Davy in 1811 (*T.* 1812, 144) by the action of sunlight on Cl + CO (hence the name *phosgene*).

*Formation.*—1. By leading CO into boiling  $\text{SbCl}_3$  (Hofmann, *A.* 70, 139; *v.* also Butlerow, *Z.* 1863, 481; Kraut, *Gm.-K. I.* 2, 386), or over hot  $\text{PbCl}_2$  or  $\text{AgCl}$  (Göbel, *J. pr. G.* 388).—2. By heating  $\text{CCl}_4$  with ZnO at  $200^\circ$  in a closed tube; or by passing  $\text{CCl}_4$  and CO through pumice in a tube heated to about  $400^\circ$ .—3. By heating  $\text{CHCl}_3$  (1 part),  $\text{K}_2\text{Cr}_2\text{O}_7$  (2 parts), and  $\text{H}_2\text{SO}_4$  (10 parts) at  $100^\circ$ , and passing the gas over Sb to absorb Cl (E. a. L.).—4. By passing Cl and CO over Pt black at about  $400^\circ$  (Schützenberger, *Bl.* [2] 10, 188; 12, 198).—5. By passing Cl and  $\text{CO}_2$  over hot C (Schiel, *J. pr. G.* 388). (For other methods *v.* Schützenberger, *B.* 2, 218; Dewar a. Cranston, *C. N.* 22, 174; Armstrong, *B.* 3, 730.)

*Preparation.*—Dry Cl and dry CO are slowly passed through a succession of large bottles freely exposed to sunlight, then through a U-tube loosely filled with pieces of Sb (to remove free Cl), and finally into a tube surrounded by snow and salt. Fresh gas should pass through the drying-bottles at as nearly as may be the same rate. 100 litres CO give 140-150 g.  $\text{COCl}_2$  in direct sunlight. Paterno (*G.* 5, 233) passes the mixed gases through a tube 400 mm. long filled with animal charcoal: combination occurs with production of heat; the tube must be cooled by a wet cloth from time to time (*v.* also Wilm a. Wischin, *A.* 147, 150).

*Properties.*—Colourless gas with penetrating odour; at  $8^\circ$  and under it is a colourless limpid liquid; the gas is soluble in acetic acid, benzene, and several liquid hydrocarbons.

*Reactions.*—1. Water absorbs  $\text{COCl}_2$  with formation of  $\text{CO}_2\text{Aq}$  and  $\text{HClAq}$ . Berthelot (*C. R.* 87, 591) gives the value  $[\text{COCl}_2\text{Aq}] = 64,600$ . 2. Alcohol forms chlorocarbonic ether  $\text{CO.Cl.OEt}$  (*q. v.*).—3. Several metals decompose  $\text{COCl}_2$ , when heated with it, to CO and metallic chloride; e.g. Sb, As, Na, Sn, Zn; potassium forms  $\text{KCl}$ ,  $\text{K}_2\text{CO}_3$ , and C.—4. With slightly moist potassium carbonate,  $\text{KCl}$ ,  $\text{H}_2\text{O}$ , and  $\text{CO}_2$  are formed.—5. Zinc oxide produces  $\text{ZnCl}_2$  and  $\text{CO}_2$ .—6. Combines with 4 vols. ammonia to form urea and  $\text{NH}_4\text{Cl}$  (Natanson, *A.* 98, 288; Fenton, *C. J.* 35, 793).

Carbon, oxysulphide of. COS. (Carbonyl sulphide.) Mol. w. 59.91. V.D.  $30.4$ .  $[\text{COS}] = 8,030$ ;  $[\text{C}_2\text{O}_2\text{S}] = 37,030$ ;  $[\text{COS}_2] = 181,010$  (Thomsen).

*Occurrence.*—According to Thom (*A. Suppl.*

5, 236), in several mineral waters, and in volcanic gases.

**Formation.**—1. By passing CO and S vapour through a red-hot porcelain tube (Thom).—2. By gently heating SO<sub>2</sub> with CS<sub>2</sub>, SO<sub>2</sub> and S also produced (Armstrong, *B.* 2, 712).—3. By action of CO<sub>2</sub> on boiling S; or by electric sparks on CO<sub>2</sub> mixed with S vapour (Cossu, *B.* 1, 117; Chevrier, *C. R.* 69, 136).—4. By leading alcohol and CS<sub>2</sub> over red-hot Cu (Carmichael, *C. J.* [2] 13, 523). For other methods *v.* Ladenburg, *B.* 1, 273; 2, 30, 53, 271; Dewar & Cranston, *C. N.* 20, 174; Salomon, *J. pr.* [2] 5, 476.

**Preparation.**—By decomposing KCNS by H<sub>2</sub>SO<sub>4</sub> Aq:  $\text{KCNS} + \text{H}_2\text{O} + 2\text{H}_2\text{SO}_4\text{Aq} = \text{COS} + \text{KHSO}_4\text{Aq} + \text{NH}_4\text{HSO}_4\text{Aq}$ . KCNS is added to a cold mixture of 5 vols. H<sub>2</sub>SO<sub>4</sub> with 4 vols. H<sub>2</sub>O as long as the whole remains liquid; if much gas comes off the vessel is cooled, if very little gas is evolved the vessel is warmed gently. The gas is passed through three U tubes, containing (1) cotton wool charged with moist HgO (to remove HCN and formic acid), (2) cuttings of unvulcanised caoutchouc (to remove CS<sub>2</sub>), (3) CaCl<sub>2</sub>; the gas is then collected over Hg (Thom). Bender (*A.* 148, 137) recommends passing the gas through a tube surrounded by snow and salt, and Hofmann (*B.* 2, 73) through wool moistened with PET<sub>3</sub>; the object in either method being to remove CS<sub>2</sub>.

**Properties.**—Colourless, heavy, gas, with a pleasant somewhat aromatic odour. Colours moist blue litmus slightly reddish. Absorbed by water; solution sometimes contains CO<sub>2</sub> and H<sub>2</sub>S. Very sol. in alcohol.

**Reactions.**—1. Burns in air to CO<sub>2</sub> and SO<sub>2</sub>. 2. At full red heat gives CS<sub>2</sub> and CO<sub>2</sub> (Berthelot, *C. R.* 87, 71).—3. With water gives CO<sub>2</sub>Aq and H<sub>2</sub>SAq.—4. With potash solution gives K<sub>2</sub>SAq and K<sub>2</sub>CO<sub>3</sub>Aq; similar reactions with NH<sub>4</sub>Aq, CaCl<sub>2</sub>Aq, and BaOAc.—5. Ammonia gas, or alcoholic NH<sub>3</sub>, gives CO.NH<sub>3</sub>.SNH<sub>3</sub> (Berthelot, *A. Ch.* [5] 30, 539).—6. Solutions of salts of copper, cadmium, lead, or silver give no pps., but on adding NH<sub>4</sub>Aq the sulphides of the metals are pps.—7. The gas is decomposed by hot mercury, copper, silver, and iron, giving sulphides; by hot sodium, giving Na<sub>2</sub>S, Na<sub>2</sub>CO<sub>3</sub>, and C.

**Carbon selenide.** Carbon and selenium do not combine directly. No definite compounds have been isolated. Rathke obtained a liquid which probably contained about 2 p.c. of a selenide of carbon (along with CCl<sub>4</sub>), by heating selenide of phosphorus with moist CCl<sub>4</sub> (*v.* *A.* 152, 181).

**Carbon, sulphides of.** Carbon disulphide, CS<sub>2</sub>, is a well-marked compound. A monosulphide, CS, probably exists. According to Löw a sesquisulphide, C<sub>2</sub>S<sub>3</sub>, can be obtained by the action of Na amalgam on CS<sub>2</sub> (*Z.* 9, 173; 10, 20). When sodium and CS<sub>2</sub> react a red-brown solid is obtained which according to Raub has the composition C<sub>2</sub>S<sub>2</sub> (*C. C.* 1870, 579).

**CARBON MONOSULPHIDE.** CS. Mol. w. unknown. S.G. 1.66. CS<sub>2</sub> was exposed to sunlight for 2 months in a U tube of special construction; the solid which had formed on the walls of the tube was removed by water, washed with CS<sub>2</sub>, and dried in H (Sidot, *C. I.*

69, 1803; 74, 180; 81, 82). CS is a red powder; insol. in water, alcohol, turpentine, and benzene. Somewhat soluble in CS<sub>2</sub> or ether. Dissolved by HNO<sub>3</sub>Aq, not by HClAq or H<sub>2</sub>SO<sub>4</sub>Aq. At 200° gives C and S. Heated with S gives CS<sub>2</sub>. CS is not produced by leading CS<sub>2</sub> over hot carbon or pumice, by heating Sb<sub>2</sub>S<sub>3</sub> with C, by reaction between CO and H<sub>2</sub>S, by reaction between CO and H<sub>2</sub>S, by reaction between CH<sub>4</sub> and SO<sub>2</sub> or S<sub>2</sub>Cl<sub>2</sub>, by heating (CN)<sub>2</sub>S, by heating Fe spiral in CS<sub>2</sub>, by electric sparks through CS<sub>2</sub>, or by reaction between CS<sub>2</sub> and hot Cu.

**CARBON DISULPHIDE.** CS<sub>2</sub>. (Thiocarbonic anhydride. Sulfocarbonic acid.) Mol. w. 75.93. [*c.* = 12.7] (Wartka *B.* 3, 80). (46.04° at 760 mm.) (Thorpe, *C. J.* 37, 362; references in this paper to other determinations). S.G. 2° 1.29215 (T.). V.D. 38. S.H. (liquid; 14°-29°) 2168 (Schüller, *P. Ergzbd.* 5, 116; *v.* also Hirn, *A. Ch.* [4] 10, 63 and 91). S.H. p. (equal mass of air = 1) 1569; (equal vol. of air = 1) 412 (Regnault). C.E. *v.* Thorpe (*l.c.*) [C, S] const. press. = -26,310; const. vol. = -25,430; liquid = -19,610; [CS<sub>2</sub>, O] = 265,130 (Thomson). For table of vapour-pressures from 0° to 50° *v.* Ramsay & Young, *C. J.* 47, 653.  $\mu_{\text{D}}$  1.6059;  $\mu_{\text{D}}$  1.6729 (at 13°) (Kundt, *W.* 4, 34). For relations between volume as gas and pressure *v.* Herwig, *P.* 137, 11°; 141, 83; 147, 161.

**Occurrence.**—In crude benzole; and in mustard oil. First prepared, in 1796, by Lampadius, by heating iron sulphide with charcoal. Composition was long uncertain. Clement & Desormes (*A. Ch.* 42, 121) regarded it as a compound of C and S; it was also thought to be a compound of S and H, and at other times of C, S, H, and N. Composition established by Vauquelin, Berzelius, and Marcet, in 1812 (*v.* *G. A.* 28, 427 n. 453; 48, 177; *S.* 9, 284; *A. Ch.* 83, 252).

**Formation.**—1. By heating S with excess of C in a porcelain tube, condensing product in vessel surrounded by cold water, shaking with NaOH Aq, drying by CaCl<sub>2</sub>, and distilling from water bath.—2. By heating C with a metallic sulphide which gives off S at a high temperature, *e.g.* CuS or Sb<sub>2</sub>S<sub>3</sub>.—3. By heating wax, sugar, resin, &c., with S.—4. By heating (CN)<sub>2</sub>S. 5. By heating CCl<sub>4</sub> with P<sub>2</sub>S<sub>5</sub> to 200° in a closed tube.

**Preparation.**—Commercial CS<sub>2</sub> is distilled off quicklime at 60°-70°, leaving a little undistilled; the distillate is shaken in contact with powdered K<sub>2</sub>MnO<sub>4</sub>, about 5 grams to 1 litre CS<sub>2</sub>, for some time (to remove H<sub>2</sub>S); it is then decanted and shaken thoroughly with Hg until fresh Hg is not blackened (various S compounds are thus removed); the liquid is poured off and again shaken with HgSO<sub>4</sub> Aq (abt. 25 g. salt per litre) until a few drops leave no trace of badly smelling residue when allowed to evaporate on filter paper; the CS<sub>2</sub> is poured off, allowed to stand in contact with CaCl<sub>2</sub>, and then distilled (from a water bath) directly into the bottle in which it is to be preserved. It is kept in perfect dark

ness (Obach, *J. pr.* [2] 26, 281; for other methods v. Sidot, *C. R.* 69, 1303; Friedburg, *B.* 8, 1616; 9, 127; Millon, *J.* 1868. 928; Cloëz, *C. R.* 69, 1356).

**Properties.**—Colourless, limpid, highly refractive, liquid; ethereal odour when quite pure; vapour even when much diluted is poisonous, it stops fermentation (v. Cloëz, *C. R.* 63, 185). According to Wartha (*B.* 3, 80; 4, 180) CS<sub>2</sub> may be solidified by placing a small quantity in the vessel of a Carré freezing machine, exhausting the air, and then opening the stopcock while continuing to exhaust; in large quantities solid CS<sub>2</sub> is obtained by mixing with absolute ether and exhausting the air by a Carré machine. Wartha also obtained a snow-like solid by blowing dry air through CS<sub>2</sub> at the ordinary temperature; according to Ballo (*B.* 4, 118) this body is a hydrate of CS<sub>2</sub>; Berthelot (*A. Ch.* [3] 46, 490) and Duclaux (*C. R.* 64, 1099) obtained such a hydrate (probably 2CS<sub>2</sub>·H<sub>2</sub>O) by evaporating CS<sub>2</sub> in moist air (v. also Venables, *Ann.* 5, 15). CS<sub>2</sub> vapour is very easily inflammable, ignition-temp. -149° (Frankland, *C. N.* 6, 3), 170° (Braun); with air or O it forms a very explosive mixture; mixed with NO and ignited it burns instantaneously with production of white light rich in actinic rays (v. Berthelot, *A. Ch.* [3] 49, 486; Berzelius a. Marcat, *S.* 9, 284; Frankland, *C. N.* 6, 3; Sell, *B.* 5, 733; Delachanal a. Mermet, *D. P.* J. 214, 483). Water dissolves about  $\frac{1}{100}$  of its weight of CS<sub>2</sub> (Sestini, *G.* 1871. 473); it is miscible in all proportions with alcohol, ether, ethereal and fatty oils, and liquid CO<sub>2</sub> (v. Tschischmidt a. Follenius, *B.* 4, 583). CS<sub>2</sub> is a solvent for fats, resins, gutta serena, alkaloids, I, S, P, &c. (v. Liebermann, *B.* 12, 1294; Gore, *P. M.* [4] 30, 414). According to Sidot, CS<sub>2</sub> is slowly changed in sunlight to CS and S (v. ante, CARBON MONOSULPHIDE).

**Reactions.**—1. Heated, strongly CS<sub>2</sub> gives C and S (Berthelot, *Bl.* [2] 11, 456; Buff a. Hofmann, *A.* 113, 129).—2. Burns in air or O to CO and SO<sub>2</sub>.—3. Decomposed by many metals; Fe is said to give CS at ord. temp. (Kern, *C. N.* 33, 253; v. also Merz a. Weith, *Z.* 11, 515); Cu at 200°-250° forms Cu<sub>2</sub>S, S, and C (M. a. W.); K gives a sulphide and C; Na at 140°-150° forms Na<sub>2</sub>S and Na<sub>2</sub>CS<sub>2</sub>, the latter body reacts with dilute HClAq to produce H<sub>2</sub>CS<sub>2</sub> (Löw, *Z.* 9, 173; 10, 120); Na amalgam according to Löw (*loc.*) gives C<sub>2</sub>S<sub>2</sub>, according to Raab (*N. R. P.* 19, 449) C<sub>2</sub>S<sub>2</sub> (v. also Hermann, *J. pr.* 79, 448; Reichl, *C. C.* 1880. 420; Guignet *Bl.* 1861. 111).—4. Hydrogen, when passed with CS<sub>2</sub> over heated Pt black, produces H<sub>2</sub>S and C; nascent H (Zn and HClAq) forms H<sub>2</sub>S and (?) C<sub>2</sub>H<sub>2</sub>S<sub>2</sub> (v. Vernon Harcourt, *C. N.* 26, 267; Cossa, *B.* 1, 117; Girard, *C. R.* 43, 396; Becquerel, *C. R.* 56, 237).—5. Chlorine reacts with CS<sub>2</sub> differently according to the conditions: dry Cl at ord. temp. gives S<sub>2</sub>Cl<sub>2</sub> and CCl<sub>4</sub>; moist Cl, or MnO<sub>2</sub> and HClAq, or other Cl producer, forms H<sub>2</sub>SO<sub>4</sub> and CS<sub>2</sub>Cl<sub>2</sub> (Kolbe, *A.* 45, 41); Cl and CS<sub>2</sub> passed through a hot tube give S<sub>2</sub>Cl<sub>2</sub> and CCl<sub>4</sub> (K.); Cl passed into boiling CS<sub>2</sub> containing a little I forms S<sub>2</sub>Cl<sub>2</sub>, CCl<sub>4</sub>, and CS<sub>2</sub>Cl<sub>2</sub> (Müller, *C. J.* 15, 41); the same products result by action of ICl<sub>3</sub> (v. Weber, *W. A. B.* 1866. 348; Hannay, *C. N.* 37, 224).—6. Chlorides which readily give

up chlorine react similarly to Cl: MoCl<sub>5</sub> and SbCl<sub>5</sub> give CCl<sub>4</sub> and S<sub>2</sub>Cl<sub>2</sub>, SbCl<sub>5</sub> also producing SbCl<sub>3</sub>S which separates into SbCl<sub>3</sub> and S (Aronheim, *B.* 9, 1788; Hofmann, *A.* 115, 264; Husemann, *A.* 117, 229); PCl<sub>5</sub> forms CS<sub>2</sub>Cl<sub>2</sub> (Carius, *A.* 113, 193), or according to Rathke (*Z.* 13, 57) C<sub>2</sub>H<sub>2</sub> and PS<sub>2</sub>Cl<sub>2</sub> (at 100°).—7. Bromine reacts in presence of I or SbBr<sub>3</sub>; 2 parts CS<sub>2</sub>, 14 parts Br, and 3 parts I, heated to 150° in a closed tube form CBr<sub>4</sub> (Bolas a. Groves, *B.* 3, 508; v. also Berthelot, *A. Ch.* [3] 53, 145). Hell a. Urech describe a compound C<sub>2</sub>S<sub>2</sub>Br<sub>2</sub> obtained by slow action of Br and CS<sub>2</sub>, and subsequent distillation (*B.* 15, 273).—8. Water, in presence of air, oxidises CS<sub>2</sub> slowly and partially to CO<sub>2</sub>Aq and SO<sub>2</sub>Aq (Berzelius); heated to 150° in a closed tube from 3 to 4 hours, CO<sub>2</sub>Aq and H<sub>2</sub>SAq are formed (Schlagdenhauffen, *J. Ph.* [3] 29, 401); evaporated in moist air a hydrate (2CS<sub>2</sub>·H<sub>2</sub>O) is said to be formed (v. Properties). 9. Warmed with sulphuric anhydride, COS, SO<sub>2</sub>, and S, are produced (Armstrong, *B.* 2, 712). 10. Mixed with carbon dioxide and passed through a hot tube, or over hot Pt black, COS is produced (Winkler).—11. Passed through a hot tube with sulphuric acid, CO, SO<sub>2</sub>, H<sub>2</sub>S, and S are formed (W.).—12. Many metallic oxides when heated with CS<sub>2</sub> react to form sulphides, sometimes also carbonates (Schlagdenhauffen, *J. Ph.* [3] 29, 401; Müller, *P.* 127, 401; Fremy, *C. R.* 35, 27).—13. Oxidising agents, e.g. KNO<sub>3</sub> or K<sub>2</sub>Mn<sub>2</sub>O<sub>8</sub>, generally produce CO<sub>2</sub> and H<sub>2</sub>SO<sub>4</sub>, sometimes CO<sub>2</sub> and H<sub>2</sub>S; As<sub>2</sub>O<sub>3</sub>, As<sub>2</sub>O<sub>5</sub>, (and salts of these) produce As<sub>2</sub>S<sub>3</sub> (v. Schlagdenhauffen, *loc.*; Cloëz a. Guignet, *C. R.* 46, 1110). 14. Boric acid and borates react at red heat to form B<sub>2</sub>S<sub>3</sub>.—15. Sulphuretted hydrogen mixed with CS<sub>2</sub> and passed over hot Cu produces CH<sub>4</sub>. 16. Alkalies in aqueous solution form carbonates and thiocarbonates (v. THIOCARBONATES, under CARBONIC ACID, &c.); alcoholic potash forms K xanthate C<sub>2</sub>H<sub>3</sub>O.CS.SK.—17. Ammonia reacts with CS<sub>2</sub> probably to form CS(NH<sub>2</sub>)<sub>2</sub> and (NH<sub>4</sub>)<sub>2</sub>CS<sub>2</sub> (Laurent, *A. Ch.* [3] 22, 103; Zouteveen, *C. C.* 1870. 821); CS<sub>2</sub> and NH<sub>3</sub> passed through a hot tube, or CS<sub>2</sub> heated in a closed tube with alcoholic NH<sub>3</sub>, produce H<sub>2</sub>S and HCNS; alcoholic NH<sub>3</sub> at ord. temp. forms (NH<sub>4</sub>)<sub>2</sub>CS<sub>2</sub>, (NH<sub>4</sub>)CNS, and CS.NH<sub>4</sub>.SNH<sub>2</sub> (Debus, *A.* 73, 26; v. also Millon, *J. Ph.* [3] 38, 401; Hofmann, *J.* 1858. 332); NH<sub>3</sub>Aq form (NH<sub>4</sub>)<sub>2</sub>CS<sub>2</sub>Aq and NH<sub>4</sub>CNSAq.

**Combinations.**—1. With many metallic sulphides to form thiocarbonates (q. v.).—2. With various ammonia derivatives; e.g. NMe<sub>3</sub>.CS<sub>2</sub>. 3. With zinc ethyl and methyl to form ZnEt<sub>2</sub>.CS<sub>2</sub> and ZnMe<sub>2</sub>.CS<sub>2</sub>, respectively.—4. With triethylphosphine to form PEt<sub>3</sub>.CS<sub>2</sub>.

**Analysis.**—Sulphur, by heating in a glass tube with Na<sub>2</sub>CO<sub>3</sub> and a little KNC<sub>3</sub>, and estimating sulphates produced, as BaSO<sub>4</sub>. Carbon, by burning with PbCrO<sub>4</sub> as in organic analyses.

**Detection and Estimation.**—Small quantities of CS<sub>2</sub> may be detected by adding alcoholic solution of potash, whereby K xanthate (C<sub>2</sub>H<sub>3</sub>O.CS.SK) is formed; on now adding solution of a copper salt a yellow pp. is produced (Vogel, *A.* 86, 369). This reaction is applied to liquids, e.g. mustard oil, by distilling a little in a current of air into alcoholic potash; coal-gas may be tested by passing through

alcoholic potash. A very delicate reaction is to bring the  $\text{CS}_2$  into contact with  $\text{PbEt}_2$ , when a characteristic carmine-red compound,  $\text{PbEt}_2\text{CS}_2$ , forms; it may be crystallised from ether. This reaction may also be applied for the estimation of  $\text{CS}_2$  (Hofmann, *B.* 13, 1732).  $\text{CS}_2$  is sometimes determined, e.g. in xanthates, by standardised  $\text{CuSO}_4\text{Aq}$  (Grete, *B.* 9, 921); the carbonates may be converted into the  $\text{Pb}$  salt (by addition of  $\text{Pb}$  acetate), and this may be decomposed by boiling with water, and the  $\text{CS}_2$  led into weighed bulbs containing alcoholic potash (Delachanal a. Mermet, *B.* 8, 1192).

#### Carbon, sulphochlorides of.

I. THIO-CARBONYL CHLORIDE.  $\text{CSCl}_2$ . Mol. w. 114.69. (709). V.D. 57.5.

**Formation.**—1. By reaction between  $\text{Cl}$  and  $\text{CS}_2$ .—2. By heating  $\text{CCl}_4$  with  $\text{S}$ .—3. By passing  $\text{CCl}_4$  and  $\text{H}_2\text{S}$  through a hot tube (Kolbe, *L.* 45, 41; Carius, *A.* 113, 193; Müller, *C. J.* 15, 41; Gustavson, *B.* 3, 989).

**Preparation.**—To dry  $\text{CS}_2$  about 2 p.c.  $\text{I}$  is added and dry  $\text{Cl}$  is passed in (a reversed condenser being attached) until the volume of liquid has increased by about  $\frac{1}{3}$ . The whole is boiled with water (to remove  $\text{S}_2\text{Cl}_2$ ); separated  $\text{S}$  is removed, water is separated, the liquid is distilled from the water-bath whereby  $\text{CCl}_4$  and  $\text{CS}_2$  distil over; the residue is then distilled till a thermometer in the liquid reaches  $175^\circ$ ; the distillate is fractionated, digested with water to remove  $\text{S}_2\text{Cl}_2$ , dried, and fractionated. About 320 g.  $\text{SCl}_2$  (*v. infra*) are thus obtained from 1 kilo.  $\text{CS}_2$ ; very finely divided silver (by reducing  $\text{AgCl}$ ) is then added little by little (the liquid being kept cold) until the whole of the liquid is soaked into the silver; it is then distilled, the distillate is shaken with water to remove traces of  $\text{S}_2\text{Cl}_2$ , dried, and fractionated (Bathke, *B.* 3, 858). The reactions are: (1)  $2\text{CS}_2 + 5\text{Cl}_2 = 2\text{CCl}_4 + \text{S}_2\text{Cl}_2$ ; (2)  $\text{SCl}_2 + 2\text{Ag} \rightarrow 2\text{AgCl} + \text{CSCl}_2$ .

**Properties and Reactions.**—Golden-red, limpid, liquid; penetrating odour, resembling that of  $\text{COCl}_2$ ; fumes in air. Exposed to light and then to a low temperature, large colourless crystals of a polymeride,  $n\text{SCl}_2$ , separate; this body is unchanged in air; melts at  $112.5^\circ$ ; is volatilised in steam; at  $180^\circ$  in a closed tube it gives  $\text{SCl}_2$ .

II. THIONYL PERCHLORIDE.  $\text{CSCl}_4$  (Bathke, *B.* 3, 858). Prepared by action of  $\text{Cl}$  on  $\text{CS}_2$  (*v.* THIONYL CHLORIDE, Preparation). A clear, golden-yellow liquid; vapour causes free flow of tears; B.P.  $146^\circ$ – $147^\circ$ ; S.G. 1.712 at  $12.8^\circ$ . Decomposed, slowly by moist air, quickly by heating with water to  $160^\circ$ , to  $\text{CO}_2$ ,  $\text{HClAq}$ , and  $\text{S}$ . Heated to  $200^\circ$  is decomposed to  $\text{CCl}_4$ ,  $\text{S}_2\text{Cl}_2$ , and a little  $\text{CSCl}_2$ . M. M. P. M.

**CARBONATES** *v.* CARBONIC ACID, CARBONATES, and THIO-CARBONATES.

**CARBON TETRA-BROMIDE** *v.* TETRA-BROMO-METHANE.

**DI-CARBON-TETRA-CARBOXYLIC ACID** *v.* ETHYLENE-TETRA-CARBOXYLIC ACID.

**CARBONIC ACID, CARBONATES, AND THIO-CARBONATES.**

**CARBONIC ACID.** A solution of  $\text{CO}_2$  in water probably contains carbonic acid,  $\text{H}_2\text{CO}_3$ . The chief reasons for this statement are as follows. The mass of  $\text{CO}_2$  dissolved by water at ordinary temperatures and small pressures (less than

760 mm.) varies as the pressure. But at pressures of 2, 3, or more atmospheres, the mass of  $\text{CO}_2$  dissolved is less than that calculated by the law of Henry a. Dalton. Khanikoff a. Longuine (*A. Ch.* [4] 11, 412) give these numbers:— $P$  = pressure in mm.,  $a$  = vol. of  $\text{CO}_2$  (measured at  $0^\circ$  and 760 mm.) dissolved by 1 vol. water at about  $15^\circ$ .

P.	a.	P.	a.
697.71	0.9441	9188.65	3.1764
809.03	1.1619	2369.02	3.4857
1289.41	1.8617	2554.0	3.7152
1469.95	2.1623	2738.33	4.0031
2002.06	2.9076	3109.51	4.5006

When the pressure is decreased to 760 mm. over water saturated with  $\text{CO}_2$  at pressures greater than 760 mm. most of the  $\text{CO}_2$  escapes, at first rapidly, then slowly; the last traces of  $\text{CO}_2$  can be removed by placing the water *in vacuo*, or by long-continued boiling. Magnesium reacts with a solution in water of  $\text{CO}_2$  to form  $\text{MgCO}_3$  and  $\text{H}$ ; the quantity of  $\text{H}$  evolved is almost exactly that calculated on the hypothesis that the reaction is  $\text{H}_2\text{CO}_3\text{Aq} + \text{Mg} = \text{MgCO}_3 + \text{H}_2$  (Ballo, *B.* 15, 3003). Water holding in solution  $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3$  dissolves considerably more  $\text{CO}_2$  than pure water;  $\text{NaHCO}_3$  (or  $\text{KHCO}_3$ ) is produced (Ballo, *loc.*).  $\text{Mg}$  reacts with aqueous solutions of  $\text{NaHCO}_3$  or  $\text{KHCO}_3$  to form  $\text{MgCO}_3$ ,  $\text{K}_2$  (or  $\text{Na}_2$ ) $\text{CO}_3$ , and  $\text{H}$  (Ballo, *loc.*). Aqueous solution of  $\text{CO}_2$  turns blue litmus wine-red, the blue colour returns on exposure to air; blue litmus in contact with  $\text{CO}_2$  at pressures of 1 $\frac{1}{2}$  to 2 atmospheres becomes vermilion-red (Malaguti, *A. Ch.* [3] 37, 206). When  $\text{CO}_2$  dissolves in water, heat is produced;  $[\text{CO}_2\text{Aq}] = 5.880$  (*Th.* 1, 260). This solution reacts thermally with alkalis as a dibasic acid; thus (Thomsen)—

n	$[\text{CO}_2\text{Aq}, 2\text{NaOH Aq}]$
1	11.016
2	20.084

The thermal value of the second formula-weight of  $\text{NaOH}$  (9.068) is considerably less than that of the first (11.016); in this respect carbonic acid behaves like sulphurous, selenious, boric, acid, &c. (*v.* ACIDS, BASICITY OF). When moist  $\text{CO}_2$  reacts with  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$  is obtained; from this a great many carbonates may be formed, the composition of which is that of metallic derivatives of a dibasic acid  $\text{H}_2\text{CO}_3$ . The aqueous solutions of carbonates are decomposed by almost all acids, not by  $\text{HClAq}$  or  $\text{H}_2\text{B}_4\text{O}_7\text{Aq}$ ; hence the *activity* of carbonic acid is small (*v.* AFFINITY). But soluble silicates are at once decomposed by  $\text{CO}_2\text{Aq}$ , and even insoluble silicates e.g. of  $\text{Ca}$ ,  $\text{Al}$ , &c. are slowly decomposed by moist  $\text{CO}_2$ . The sulphur analogue of carbonic acid— $\text{H}_2\text{CS}_3$ —has been isolated. Finally various derivatives, both of  $\text{CO}(\text{OH})_2$  and  $\text{C}(\text{SH})_2$  are known; viz.  $\text{COCl}_2$ ,  $\text{COBr}_2$ ,  $\text{CO}(\text{NH}_2)_2$ ,  $\text{COS}$ ,  $\text{CSCl}_2$ ,  $\text{CS.NH}_2\text{SH}$ ,  $\text{CS}(\text{NH}_2)_2$ .

**CARBONATES.** Normal carbonates have the composition  $\text{M}_2\text{CO}_3$  or  $\text{MCO}_3$ . Certain acid carbonates,  $\text{MHCO}_3$ , have also been isolated; very few of these are known as definite solids, the principal are when  $\text{M} = \text{Na}$ ,  $\text{K}$ ,  $\text{NH}_4$  (?  $\text{Li}$ ). Some insoluble normal carbonates, e.g.  $\text{Ba}$ ,  $\text{Mg}$ ,  $\text{Fe}$ , dissolve in water saturated with  $\text{CO}_2$ ; at a

pressure of 4 or 5 atmos. acid carbonates are probably formed. Many 'basic' carbonates exist; these are most simply represented by the general formula  $x\text{MO}(\text{or } \text{M}_2\text{O}_3) \cdot y\text{CO}_2 \cdot z\text{H}_2\text{O}$ . A few double carbonates are also known, usually compounds of alkali carbonates with others, e.g.  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{MgCO}_3$ ;  $\text{K}_2\text{CO}_3 \cdot \text{NiCO}_3 \cdot 4\text{H}_2\text{O}$ . Several ethereal carbonates are known, derived from the hypothetical ortho-carbonic acid  $\text{C}(\text{OH})_4$ ; e.g.  $\text{C}(\text{OR})_4$ ,  $\text{C}(\text{OPr})_4$  (v. CARBONIC ETHERS).

**Formation.**—1. By reaction between metallic oxides or hydroxides and  $\text{CO}_2$  in presence of water; the oxides which act as weak bases,  $\text{Fe}_2\text{O}_3$ ,  $\text{Al}_2\text{O}_3$ , &c., do not combine with  $\text{CO}_2$  when dry.—2. By pptn. from solutions of salts by alkali carbonate solutions; only the salts of  $\text{BaO}$ ,  $\text{SrO}$ ,  $\text{CaO}$ ,  $\text{Ag}_2\text{O}$ , and  $\text{Hg}_2\text{O}$  yield normal carbonates; other salts give basic carbonates containing less  $\text{CO}_2$  relatively to  $\text{MO}$ , the weaker is the oxide  $\text{MO}$ , and the warmer and more dilute is the solution; salts of such weak bases as  $\text{Fe}_2\text{O}_3$ ,  $\text{Al}_2\text{O}_3$ , and  $\text{SnO}$  give pps. of hydrates free from  $\text{CO}_2$ .—3. By strongly heating the alkali or alkaline earth salts of organic acids.—4. In some cases by reaction between  $\text{CO}_2$  and a metal; e.g.  $\text{Mg}$ ,  $\text{Fe}$ ,  $\text{Zn}$ .

**Solubility in water.**—Carbonates of  $\text{Na}$ ,  $\text{K}$ ,  $\text{Rb}$ , and  $\text{Cs}$ , are easily soluble in water; carbonates of  $\text{Li}$  and  $\text{Tl}$  are much less soluble; other carbonates are nearly, or quite, insoluble. All carbonates are soluble, to some extent, in water in which  $\text{CO}_2$  has been dissolved. All, except those of  $\text{NH}_4$ ,  $\text{Rb}$ , and  $\text{Cs}$ , are insoluble in alcohol.

**Reactions.**—1. All carbonates, except those of the fixed alkalis, are wholly or partially decomposed by heat alone;  $\text{BaCO}_3$  begins to decompose only at a full white heat,  $\text{SrCO}_3$  at beginning white heat, and  $\text{CaCO}_3$  at full red heat;  $\text{Ag}_2\text{CO}_3$  gives up  $\text{CO}_2$  at  $200^\circ$ , and at  $250^\circ$  the  $\text{Ag}_2\text{O}$  gives off  $\text{O}$  and leaves  $\text{Ag}$ ;  $\text{MnCO}_3$  heated to  $200^\circ$ – $300^\circ$  in air gives  $\text{MnO}_2$  and  $\text{CO}_2$ .—2. Heated in steam all carbonates are decomposed to hydrates and  $\text{CO}_2$  (v. Rose, *P.* 85, 99 a. 279).—3. Carbonates are decomposed by aqueous solutions of most acids at ordinary temperatures with evolution of  $\text{CO}_2$ ;  $\text{HCN}$  and  $\text{H}_2\text{B}_2\text{O}_4$  Aq, however, do not decompose carbonates.—4. Solid carbonates are decomposed by heating with solid boric acid, silica, potassium dichromate, and some other salts. Sulphuretted hydrogen reacts with many insoluble carbonates suspended in water, e.g. of  $\text{Sr}$ ,  $\text{Ba}$ ,  $\text{Ca}$ ,  $\text{Zn}$ ,  $\text{Mg}$ ,  $\text{Li}$ , to form sulphides and  $\text{CO}_2$ ; the change proceeds the further the more water is present (Naudin a. Montholon, *C. R.* 83, 58).—5. The more stable carbonates when heated with carbon give  $\text{CO}$ .—6. Alkali carbonates heated in phosphorus vapour give phosphates and  $\text{C}$ .—7. Aqueous solutions of acid carbonates do not usually affect the colour of litmus; they give an alkaline reaction with rosolic acid.

**Detection and Estimation.**—Usually detected by decomposing by an acid and examining action of gas evolved on  $\text{Ca}$  Aq. Usually estimated by decomposing weighed quantity by acid and determining  $\text{CO}_2$  by loss.

**Aluminium carbonate.** Existence doubtful. Pp. produced by alkaline carbonates with  $\text{Al}$  salts variously formulated as a highly hydrated basic carbonate (Munspratt, *C. J.* 2, 206; Lang-

lois, *A. Ch.* [3] 48, 502; Wallace, *C. Gazette*, 1858. 410); as a compound of  $\text{Al}_2\text{O}_3$  and a small quantity of the carbonate employed, e.g.  $\text{Al}_2(\text{HO})_4 \cdot 2\text{NH}_4\text{HCO}_3$  (Rose, *P.* 41, 462); and as pure  $\text{Al}_2\text{O}_3$  (Barratt, *C. J.* 13, 190). By Wibain and Renoul the pp. in the cold is said to be  $2\text{Al}_2\text{O}_3 \cdot \text{CO}_2 \cdot 8\text{H}_2\text{O}$  and to decompose about  $30^\circ$  (*C. R.* 88, 433) (v. also H. Rose, *P.* 91, 460; Parkmann, *Am. S.* [2] 34, 324).

**Ammonium carbonates.** Three definite salts seem to exist, the normal, the acid, and the sesqui, carbonate (Divers, *C. J.* [2] 8, 171). The last is sometimes regarded as a compound of the first and second (Devile, *C. R.* 34, 880). Divers considers the compositions of the three salts to be:

Normal carbonate,  $2\text{CO}_2 \cdot 4\text{NH}_3 \cdot 4\text{H}_2\text{O}$ .

Sesquicarbonate,  $3\text{CO}_2 \cdot 4\text{NH}_3 \cdot 4\text{H}_2\text{O}$ .

Acid carbonate,  $4\text{CO}_2 \cdot 4\text{NH}_3 \cdot 4\text{H}_2\text{O}$ .

Rose's hyperacid carbonate may be the fourth term of this series.

I. **Normal carbonate**  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{H}_2\text{O}$ . Prepared (1) by adding excess of  $\text{NH}_3$  Aq to a warm conc. solution of the commercial carbonate; (2) by warming water with the ordinary carbonate, and allowing solution to cool and crystallise; after this has been done repeatedly the cold mother liquor from the last crop of crystals deposits normal carbonate. Large elongated plates, freely soluble in water, insol. alcohol, sparingly sol.  $\text{NH}_4$  Aq. Decomposes in air to  $\text{NH}_4\text{HCO}_3$ , with evolution of  $\text{NH}_3$ , and at  $85^\circ$  to  $\text{NH}_3$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$ . Is converted into carbamate by digestion in closed vessel at  $20^\circ$ – $25^\circ$ .

II. **Acid carbonate**  $\text{NH}_4\text{HCO}_3$ . Occurs in guano-deposits (Ulex, *A.* 61, 44). Prepared by saturating  $\text{NH}_3$  Aq, or solution of  $\text{NH}_3$  sesquicarbonate, with  $\text{CO}_2$ , and drying over  $\text{H}_2\text{SO}_4$  and  $\text{KOH}$ . *S.* ( $0^\circ$ ) 11.9; ( $10^\circ$ ) 15.85; ( $20^\circ$ ) 21; ( $30^\circ$ ) 27 (Dibbitts, *J. Agr.* [2] 10, 417). This is the stable salt to which the other  $\text{NH}_4$  carbonates are converted. Large, transparent, trimetric crystals. Dimorphous, but never isomorphous with  $\text{KHCO}_3$  (Devile). Solution at  $36^\circ$  evolves  $\text{CO}_2$ ; even at ordinary temperature unstable in solution.

III. **Sesquicarbonate.**  $(\text{NH}_4)_2\text{CO}_3 \cdot 2\text{NH}_4\text{HCO}_3$ . By slowly heating the commercial salt till melted and then cooling; or crystallises from warm solution of the same salt mixed with  $\text{NH}_4$  Aq. Large transparent crystals, losing  $\text{H}_2\text{O}$  and  $\text{NH}_3$  in air and giving  $\text{NH}_4\text{HCO}_3$ . *S.* ( $13^\circ$ ) 25; ( $17^\circ$ ) 30; ( $32^\circ$ ) 37; ( $41^\circ$ ) 40; ( $49^\circ$ ) 50 (Berzelius). Solution easily decomposes with evolution of  $\text{CO}_2$ .

Another carbonate— $(\text{NH}_4)_2\text{CO}_3$ —appears to exist in the mother-liquor from the preparation of the sesquicarbonate (Divers). The commercial carbonate is probably  $3\text{NH}_3 \cdot 2\text{CO}_2 \cdot \text{H}_2\text{O}$ . It generally contains 1 p.c.  $\text{H}_2\text{O}$  in excess of this formula, and a little ammonia. Prepared (1) by dry distillation of animal matter and subsequent purification by redistillation with charcoal; (2) by heating to redness  $\text{NH}_4\text{Cl}$  and  $\text{CuCO}_3$  in retort with receiver. The first products are  $\text{H}_2\text{O}$  and  $\text{NH}_3$  carbamate, subsequent distillation produces the commercial carbonate. A white, transparent, fibrous mass, with strong ammoniacal smell, volatile, but not without some decomposition. Solution strongly alkaline.

**Barium carbonate.**  $\text{BaCO}_3$ . By adding  $(\text{NH}_4)_2\text{CO}_3$  aq. to  $\text{BaCl}_2$  aq. or  $\text{Ba}(\text{NO}_3)_2$  aq.; or  $\text{Na}_2\text{CO}_3$  aq. to  $\text{BaSAq}$ ; or (impure) by strongly heating a mixture of  $\text{BaSO}_4$ , charcoal, and  $\text{K}_2\text{CO}_3$ , and extracting the  $\text{K}_2\text{S}$  formed with water, leaving  $\text{BaCO}_3$ .  $\text{S.} = 0$ ; in water saturated with  $\text{CO}_2$  at 4 to 6 atmos. pressure  $\text{S.} = .75$ . The salt remains in solution at ordinary pressure, but is completely ppt. on boiling (Wagner, *J. pr.* 102, 233; *J.* 186, 135). Found native as *Witherite*. This mineral can be obtained artificially from amorphous  $\text{BaCO}_3$  by crystallising from fused  $\text{KCl}$  and  $\text{NaCl}$  (Bourgeois, *Bl.* [2] 37, 447). A soft white poisonous powder, easily soluble in solution of  $\text{NH}_4\text{Cl}$ ,  $\text{NH}_4\text{NO}_3$ , or ammonium succinate. Above red heat in presence of  $\text{O}$  it yields  $\text{BaO}$  and  $\text{CO}_2$ . Decomposed at red heat by aqueous vapour especially in presence of chalk. Yields  $\text{BaSO}_4$  when shaken with  $\text{K}_2\text{SO}_4$  or  $\text{Na}_2\text{SO}_4$  aq. and is completely decomposed by boiling with  $\text{NH}_4\text{Cl}$  aq.

**Barium acid carbonate.**  $2\text{BaCO}_3 \cdot \text{CO}_2$ , described by Boussingault (*A. Ch.* [2] 29, 289) but Rose thinks it cannot exist except in solution.

**Beryllium carbonate.** A compound of variable composition is obtained by exposing  $\text{Be}(\text{HO})_2$  to air, ppg. beryllium salts with alkaline carbonates, or boiling solution of double  $\text{Be} \cdot \text{NH}_4$  carbonate. The composition of pp. by last method is  $5\text{BeO} \cdot \text{CO}_2 \cdot 6\text{H}_2\text{O}$  (Schaffgotsch). Decomposed by boiling water, soluble in alkaline carbonates. The salt  $\text{BeCO}_3 \cdot 4\text{H}_2\text{O}$  is obtained by passing  $\text{CO}_2$  through water containing basic salt in suspension and evaporating over  $\text{H}_2\text{SO}_4$  in atmosphere of  $\text{CO}_2$ .

**Beryllium ammonium carbonate.**  $2(\text{BeCO}_3 \cdot (\text{NH}_4)_2\text{CO}_3) \cdot \text{Be}(\text{HO})_2 \cdot 2\text{H}_2\text{O}$ . By dissolving  $\text{BeO}$  in conc.  $\text{Am}_2\text{CO}_3$  aq. at gentle heat, then boiling till solution becomes cloudy, filtering, and adding conc. alcohol; crystals are drained, washed with alcohol, and dried by pressing between paper (Humpidge, *Pr.* 39, 14). By similar method Deville (*A. Ch.* [3] 44, 5) obtained a salt of formula  $3(\text{BeCO}_3 \cdot (\text{NH}_4)_2\text{CO}_3) \cdot \text{Be}(\text{HO})_2$  soluble in cold, and decomposed by hot water.

**Bismuth carbonate.**  $\text{Bi}_2\text{O}_3 \cdot \text{CO}_2$  (Berzelius) a white pp. obtained by dropping a solution of  $\text{Bi}_2\text{NO}_3$  into an alkaline carbonate. According to Lefort this pp. contains  $\frac{1}{2} \text{H}_2\text{O}$  evolved at  $100^\circ$ . Heated strongly yields  $\text{Bi}_2\text{O}_3 \cdot 3(\text{BiO})_2\text{CO}_3 \cdot 2\text{BiO}_3 \cdot 3\text{H}_2\text{O}$ . Occurs native as *Bismuthite* in South Carolina.

**Cadmium carbonate.**  $\text{CdCO}_3$  (?) Occurs native with  $\text{ZnCO}_3$ . By ppg. solution of a cadmium salt with  $(\text{NH}_4)_2\text{CO}_3$  aq. The white pp. is said to contain water, which is lost at  $80^\circ$  and  $20^\circ$ ; and at a higher temp. to lose  $\text{CO}_2$  and leave  $\text{CaO}$  (Lefort, *Ch. F.* [3] 12, 78); Rose (*P.* 85, 301) says pp. is nearly represented by  $\text{CdCO}_3$ . Moist  $\text{Cd}(\text{HO})_2$  absorbs  $\text{CO}_2$  and at  $300^\circ$  loses all its water, leaving  $2\text{CdO} \cdot \text{CdCO}_3$ .

**Cesium carbonate.**  $\text{Cs}_2\text{CO}_3$ .  $\text{S.}$  alcohol ( $19^\circ$ ) = 11.1. Ill-defined hydrate, deliquescent crystals separate from a syrupy solution. On melting these leave  $\text{Cs}_2\text{CO}_3$  as sandy powder. *Acid carbonate*,  $\text{Cs}_2\text{HCO}_3$ , crystallises from aqueous solutions in large prisms.

**Calcium carbonate.**  $\text{CaCO}_3$ .  $\text{S.}$  (cold) = .0094; ( $100^\circ$ ) = 1.13 (Fresenius, *A.* 59, 117);  $\text{S.}$  ( $0^\circ$  in water saturated with  $\text{CO}_2$ ) = .07, ( $10^\circ$ ) = .088

(Lassaigne, *J. Chem. Med.* 1848. 312; Schlesinger, *C. J.* [2] 10, 788).

**Occurrence.**—Native; in rhombohedra (hexagonal) as *calc spar*,  $\text{S.G.}$  2.69–2.75; and in right rhombic prisms (trimetric),  $\text{S.G.}$  2.92–3.28, as *aragonite*; also abundantly as chalk, limestone, &c. Formed when hydrated or anhydrous  $\text{CaO}$  is exposed to moist air; but not by action of  $\text{CO}_2$  on dry  $\text{CaO}$ .

**Preparation.**—1. By ppg.  $\text{CaCl}_2$  aq. by  $(\text{NH}_4)_2\text{CO}_3$  aq. From not too dilute solutions below  $30^\circ$ , it is ppt. entirely as *calc spar*; above  $30^\circ$  the pp. contains *aragonite*, in gradually increasing quantity as the temp. rises, until about  $90^\circ$  the pp. is almost entirely *aragonite*.  $\text{CaCO}_3$  which separates as *calc spar* from a cold, not too dilute, solution of the acid carbonate, is deposited partly in *aragonitic* form on addition of a very little  $\text{PbCO}_3$ ,  $\text{CaSO}_4$ , or  $\text{SrSO}_4$  (Cromer, *J. f. Mineral.* 1871. 288). The *aragonite* tends to change to *calc spar* form if left under cold solution. Can be obtained in form of calcite from ppt. carbonate by crystallising from fused  $\text{NaCl}$  and  $\text{KCl}$  (Bourgeois, *Bl.* [2] 37, 447).

**Properties and Reactions.**—Tasteless, white, slightly alkaline; easily soluble, when recently ppt., and to a certain extent even when it becomes crystalline, in aqueous solutions of  $(\text{NH}_4)_2\text{CO}_3$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NH}_4\text{NO}_3$ , and ammonium succinate. These salts, therefore, prevent complete ppt. of calcium as carbonate. At full red heat is decomposed into  $\text{CO}_2$  and  $\text{CaO}$ . Temp. of decomposition is lowered by passing air or steam over the  $\text{CaCO}_3$ . In closed tube fuses to marble-like substance. Boiling ammonium chloride solution decomposes  $\text{CaCO}_3$  forming  $\text{CaCl}_2$  and  $(\text{NH}_4)_2\text{CO}_3$ . Sulphur decomposes  $\text{CaCO}_3$  forming  $\text{CaSO}_4$  without previous formation of  $\text{H}_2\text{S}$  (Podacci, *G.* 1874. 177). The sulphur is oxidised at expense of oxygen of water (Bignatelli & Pelleggio, *G.* 1874. 536), the formation of sulphuric acid is preceded by that of penta- and tetra-thionic acids (Bellucci, *S.* 1874. 179). A salt of the formula  $\text{CaCl}_2 \cdot 2\text{CaCO}_3 \cdot 6\text{H}_2\text{O}$  was obtained by Pelouze (*Bl.* [2] 3, 183).

**Hydrates:** above  $30^\circ$   $\text{CaCO}_3$  is ppt.; below  $30^\circ$  hydrates are formed containing amounts of water (10–27 p.c.) which vary with the temp. and time occupied in ppg. From a solution of lime in sugar-water cooled to  $0^\circ$ – $2^\circ$ , a hydrate  $\text{CaCO}_3 \cdot 6\text{H}_2\text{O}$ , decomposed at  $30^\circ$ , is obtained; while the same solution at a little higher temp. yields  $\text{CaCO}_3 \cdot 5\text{H}_2\text{O}$  crystallising in rhombohedra,  $\text{S.G.}$  1.783, decomposed above  $1^\circ$  even in water (Pelouze, *Bl.* [2] 5, 183). Same hydrate found by Scheerer (*P.* 18, 383) and Ramsdell (*B.* 4, 469). A gelatinous hydrate formed by action of  $\text{CO}_2$  on  $\text{CaO}$  and water is described by Boudon-neau (*Bl.* [2] 23, 100).

**Acid carbonate**  $\text{CaH}_2(\text{CO}_3)_2$  (?) is known only in solution; obtained by passing  $\text{CO}_2$  into cold water containing suspended  $\text{CaCO}_3$ . Decomposed with separation of  $\text{CaCO}_3$  on exposure to air, or more quickly on boiling.

**Basic carbonate**  $2\text{CaO} \cdot \text{CO}_2$ . Obtained from  $\text{CaCO}_3$  at a moderate red heat. Hardens by action of water, forming  $\text{CaCO}_3 \cdot \text{CaO} \cdot \text{H}_2\text{O}$ , which is also produced by exposing  $\text{CaO}$  to moist air. This hydrate gives  $2\text{CaO} \cdot \text{CO}_2$  at low

red heat, and at strong red heat gives off  $\text{CO}_2$  and  $\text{H}_2\text{O}$  (Fuchs, *P.* 27, 601).

**Cerium carbonate**  $\text{Ce}_2(\text{CO}_3)_3 \cdot 9\text{H}_2\text{O}$  by exposing  $\text{Ce}_2\text{O}_3$  to air or by ppt. A white powder, partially converted on heating strongly in air into  $\text{Ce}_2\text{O}_3$ .

**Chromous carbonate**  $\text{CrCO}_3$ . An amorphous greyish-white substance, prepared by heating a chromous salt with  $\text{Na}_2\text{CO}_3\text{Aq}$  out of contact with the air (Moissan, *A. Ch.* [5] 25, 401).

**Cobalt carbonate**  $\text{CoCO}_3$ . By heating  $\text{CoCl}_2$  with  $\text{CaCO}_3$  to  $150^\circ$  in sealed tube for 18 hrs., or by decomposing  $\text{CoCl}_2$  with a solution of  $\text{NaHCO}_3$  supersaturated with  $\text{CO}_2$  and heated to  $140^\circ$  in a strong vessel allowing slow escape of  $\text{CO}_2$ . Light, rose-coloured, sandy powder; microscopic rhombohedr.; not attacked by acids in the cold (Sénarmont, *A. Ch.* [3] 30, 129).

**Hydrated carbonates and double salts** are formed on adding cobalt solutions to alkaline carbonates. Hot or cold, not too dilute, solutions yield a rose-coloured pp., which dried at  $100^\circ$  is  $2\text{CoCO}_3 \cdot 3\text{Co}(\text{HO})_2$  (Setterberg, *P.* 19, 55; Winkelblech, *A.* 13, 148; Rose, *ibid.* 80, 237). Boiling water partially converts it into  $\text{Co}_2\text{O}_3$  (Field, *C. J.* 14, 50); digested with  $\text{NaHCO}_3$  or  $(\text{NH}_4)\text{HCO}_3\text{Aq}$  yields  $3\text{CoCO}_3 \cdot \text{H}_2\text{O}$  (Dewille, *A. Ch.* [3] 33, 75). Hot very dilute solutions yield blue  $\text{CoCO}_3 \cdot 2\text{Co}(\text{HO})_2\text{aq}$ . Heated above  $150^\circ$  both pps. give off  $\text{H}_2\text{O}$  and  $\text{CO}_2$ , yielding  $\text{Co}_2\text{O}_3$  (Rose).

**Cobalt-potassium carbonate**  $(\text{CoKH})(\text{CO}_3) \cdot 4\text{H}_2\text{O}$ . Rose-coloured crystals, prepared by action of excess of  $\text{KHCO}_3\text{Aq}$  on  $\text{Co}(\text{NO}_3)_2$  or  $\text{CoSO}_4\text{Aq}$ . Decomposed by water (Rose; Dewille). Dewille also obtained  $\text{CoK}_2(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$ .

**Cobalt-sodium carbonate**  $\text{CoNa}_2(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$ . Prismatic, and  $\text{CoNa}_2(\text{CO}_3)_2 \cdot 10\text{H}_2\text{O}$  dark red, crystals; obtained together by the action of  $\text{Co}_2\text{NO}_3\text{Aq}$  on solutions of  $\text{Na}$  sesquicarbonate (Dewille).

**Copper carbonate**. Unknown except in solution. Obtained by dissolving the ppt. basic carbonate in  $\text{CO}_2\text{Aq}$  at 4-6 atmospheres pressure (Wagner, *J. pr.* 102, 233).

**Hydrated basic carbonates**.  $\text{CuCO}_3 \cdot \text{CuO} \cdot \text{H}_2\text{O}$  occurs native as *malachite*. Prepared by ppg. a cupric salt with an alkaline carbonate. The pp. at first is greenish blue, and is said to contain 1 mol.  $\text{H}_2\text{O}$ ; left in contact with liquid and washed it has above composition and is dark green. Heated to  $200^\circ$  yields malachite. Boiled with water & yields  $\text{CO}_2$  and  $\text{CuO}$  (H. Rose; Field, *C. J.* 14, 71). Digested with  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  at  $48.8^\circ$  it is converted into  $\text{CuCO}_3 \cdot 5\text{CuO}$ , a dense black powder, which is also obtained by prolonged boiling  $\text{CuSO}_4\text{Aq}$  with  $\text{Am.H}_2(\text{CO}_3)_3$ , filtering from  $\text{CuCO}_3 \cdot \text{Cu}(\text{HO})_2$ , and adding more  $\text{CuSO}_4$  (Field). Digested with  $\text{Na}_2\text{CO}_3$  yields  $\text{CuCO}_3 \cdot 7\text{CuO} \cdot 5\text{H}_2\text{O}$ .

The basic salt  $2\text{CuCO}_3 \cdot \text{Cu}(\text{HO})_2$  occurs native as *azurite* in blue monoclinic crystals. Boiled with water yields  $\text{CuO}$  and evolves  $\text{CO}_2$ . With hot  $\text{NaHCO}_3$  yields a blue solution which after protracted boiling, deposits  $\text{CuCO}_3 \cdot \text{CuO} \cdot \text{H}_2\text{O}$  (Field). Prepared artificially by secret process (Phillips, *A. Ch.* [2] 7, 44). *Azurite* can be formed from malachite at ordinary temps. by addition of  $\text{CO}_2$  and abstraction of  $\text{H}_2\text{O}$  in presence of a dehydrating agent and  $\text{CO}_2$  at high

temp. (Weibel, *J. für Mineral.* 1873. 245). Crystallised  $\text{Cu}(\text{NO}_3)_2$  heated with  $\text{CuCO}_3$  under a pressure of 54 atmospheres yields crystalline warty mass of *azurite* (Debray).

**Double salts. Potassic-cupric carbonate**  $5\text{CuO} \cdot \text{K}_2\text{O} \cdot \text{CO}_3 \cdot 10\text{H}_2\text{O}$ . A dark-blue silky mass, obtained by adding  $\text{Cu}(\text{NO}_3)_2$  to  $\text{KHCO}_3$ .

**Sodic-cupric carbonate**  $\text{CuNa}_2(\text{CO}_3)_2 \cdot 6\text{H}_2\text{O}$ . By action of  $\text{NaHCO}_3$  on  $\text{CuCO}_3 \cdot \text{CuO} \cdot \text{H}_2\text{O}$  at  $40^\circ$ - $50^\circ$ . Rhombic prisms.

**Cuprammonium carbonate**  $(\text{NH}_4)_2\text{CuCO}_3$ . Obtained as dark-blue crystals by dissolving basic carbonate of copper in  $\text{Am}_2\text{CO}_3$  and pouring solution into alcohol. Water decomposes it into  $\text{Am}_2\text{CO}_3$  and  $\text{CuCO}_3 \cdot \text{CuO} \cdot \text{Cu}(\text{HO})_2$  (Favre, *Traité de Chem.* par Pelouze et Frémy). Also formed when  $\text{CuO}$  or  $\text{Cu}$  is digested in  $\text{NH}_3\text{Aq}$  with access of air.

**Didymium carbonate**.  $\text{Di}_2(\text{CO}_3)_3$ . A red crystalline powder obtained by passing  $\text{CO}_2$  into water containing suspended  $\text{Di}_2\text{O}_3\text{H}_2$ . A hydrated carbonate is obtained, as a very slightly rose-coloured pp., by adding an alkaline carbonate to solution of a  $\text{Di}$  salt. Loses  $\frac{2}{3}\text{H}_2\text{O}$  and a little  $\text{CO}_2$  at  $100^\circ$  (Marignac).

**Indium carbonate**.  $\text{In}_2(\text{CO}_3)_3$ . White, gelatinous pp., soluble in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ , and ppt. on boiling; insoluble in solution of fixed alkali carbonates (Winkler, *J. pr.* 94, 1).

**Iron carbonates**. **Ferric carbonate** does not appear to exist (Gmelin; Soubeiran, *A. Ch.* [2] 41, 326). Double salts of ferric and alkaline carbonates appear to exist in solution, as the pp. of ferric hydrate obtained by conc. alkaline carbonate solutions gradually redissolves, whereas pure well-washed  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$  does not dissolve in these solutions.

**Ferrous carbonate**,  $\text{FeCO}_3$ , occurs abundantly as *spathe ore*. Prepared by methods similar to those described for  $\text{CoCO}_3$  (*q. v.*). It is a greyish-white crystalline solid, composed of minute rhombohedra; scarcely attacked by dilute acids, nearly unchanged in dry air. It is darker and less alterable the higher the temperature at which it has been formed, and the longer it has been heated (Sénarmont, *A. Ch.* [3] 30, 129). *Spathe ironstone* dissolves under pressure in water saturated with  $\text{CO}_2$  ( $S. = 72$ ), and is deposited as a black amorphous pp. on boiling (Wagner, *J.* 1867, 135).

**Hydrated ferrous carbonate**,  $\text{FeCO}_3 \cdot \text{H}_2\text{O}$ , occurs native. Amorphous, white, earthy, little altered in air, scarcely decomposed by acids at ordinary temps. (Moissan, *C. R.* 59, 238). The hydrate obtained by ppg. solution of a ferrous salt with an alkaline carbonate rapidly decomposes on exposure to air. It can be obtained fairly pure, as a greenish tasteless powder, by ppg. ferric-free ferrous sulphate with normal or acid alkaline carbonates. The salts are dissolved in de-aerated water, the pp. washed by decantation out of contact with air, and dried in  $\text{CO}_2$ . If dry it is fairly permanent; if moist it gives off  $\text{H}_2\text{O}$  and  $\text{CO}_2$ ; but if mixed with sugar the change is less rapid.

**Ferrous-hydroferrous carbonate**. Solution of  $\text{CO}_2$  dissolves  $\text{FeCO}_3$  and  $\text{Fe}$ ; the latter with evolution of  $\text{H}_2$ .

**Lanthanum carbonates**.  $\text{La}_2(\text{CO}_3)_3 \cdot 8\text{H}_2\text{O}$ . Found native as *Lanthanite* in four-sided plates or minute tables of the trimetric system.

The carbonate obtained by ppn. forms a white gelatinous mass which changes to shining crystalline scales.  $2\text{La}(\text{CO}_3)_2 \cdot 15\text{H}_2\text{O}$ ; ppd. by  $\text{Na}_2\text{CO}_3\text{Aq}$  from  $\text{La}_2\text{SO}_4\text{Aq}$ , and dried at ordinary temperature. Micaceous scales with silky lustre (Hormann, *J. pr.* 82, 385).

**Lead carbonate.**  $\text{PbCO}_3$ . Occurs native in trimetric crystals as *white lead ore* or *cerussite*. Has also been found on bronze objects from Pompeii (Luca, *C. R.* 84, 1457). Prepared by ppg.  $\text{Pb}(\text{NO}_3)_2\text{Aq}$  with excess of alkaline carbonates in the cold (Berzelius; Lefort, *J. Ph.* [3] 15, 26). According to Rose (*A.* 89, 235) these pps. are all hydrocarbonates, the ratio of hydrate to carbonate increasing with the temp. and dilution of the solutions. Bodies of the same composition are formed by direct action of  $\text{CO}_2$  on  $\text{Pb}(\text{HO})_2$ , but differ in being amorphous and opaque, instead of consisting of minute transparent crystalline grains.

**White lead** is a hydrocarbonate presenting varieties of composition represented by (1)  $2\text{PbCO}_3 \cdot \text{PbO} \cdot \text{H}_2\text{O}$ ; (2)  $5\text{PbCO}_3 \cdot 3\text{PbO} \cdot \text{H}_2\text{O}$ ; (3)  $3\text{PbCO}_3 \cdot \text{PbO} \cdot \text{H}_2\text{O}$  (Mulder, *A.* 33, 242); (4)  $5\text{PbCO}_3 \cdot \text{PbO} \cdot \text{H}_2\text{O}$  (Phillips, *C. J.* 4, 165). Prepared by (1) *Dutch method*. Thin lead sheets are placed over gallipots containing weak acetic acid ( $2\frac{1}{2}$  p.c.); the pots are embedded in fermenting tan at a temp. of  $60^\circ$ – $65^\circ$ . The metal disappears in a few weeks. Oxide of lead is first formed, and dissolved by the acetic acid, forming a basic acetate, and this is decomposed by the  $\text{CO}_2$  evolved from the tan. (2)  $\text{PbO}$  is mixed with water and about 1 p.c. of  $\text{Pb}$  acetate, and  $\text{CO}_2$  is passed over it.  $\text{Pb}(\text{NO}_3)_2$  has been used instead of acetate. Nearly insol. in sat.  $\text{CO}_2\text{Aq}$  even under pressure (Wagner). The ppd. carbonate has  $S. = .05$  in sat.  $\text{CO}_2\text{Aq}$ .

**Lead-sodium carbonate.**  $4\text{PbCO}_3 \cdot \text{Na}_2\text{CO}_3$  (Berzelius, *P.* 47, 199).

**Lead-chloro-carbonate.** A compound of the chloride and carbonate of lead is obtained as a pp. by the action of  $\text{CO}_2$  under pressure on  $\text{PbCl}_2$  (Miller, *C. J.* [2] 8, 37).

**Lithium carbonate.**  $\text{Li}_2\text{CO}_3$ .  $S. (0^\circ) = 1.539$ ;  $(50^\circ) = 1.181$ ;  $(100^\circ) = .728$  (Bevade, *Bl.* [2] 43, 123). Found in many mineral waters. Prepared by dissolving an excess of  $(\text{NH}_4)_2\text{CO}_3$  in conc.  $\text{LiClAq}$ , and washing resulting pp. with alcohol, or by strongly heating  $\text{Li}$  acetate. Not decomposed by heat. Melts at low red heat, and solidifies to a vitreous mass on cooling. The solution is alkaline and decomposes  $\text{NH}_4$  salts, but is decomposed by  $\text{Ba}(\text{HO})_2$  and  $\text{Ca}(\text{HO})_2$ . By slow evaporation the solution deposits salt in small prisms. Water saturated with  $\text{CO}_2$  dissolves it more readily than pure water.

**Magnesium carbonate.**  $\text{MgCO}_3$ . Occurs native as *magnesite*, in rhombohedral crystals isomorphous with calc spar; infusible; dissolves slowly in acids. Prepared (1) By suspending in water the washed pp. obtained by adding solution of an alkaline carbonate to solution of a  $\text{Mg}$  salt (which always contains  $\text{MgO} \cdot \text{H}_2\text{O}$ ), passing  $\text{CO}_2$  through the liquid till pp. is dissolved, and evaporating by heat (Rose, *P.* 42, 366); (2) By heating  $\text{MgSO}_4\text{Aq}$  with  $\text{Na}_2\text{CO}_3\text{Aq}$  to  $160^\circ$  in a sealed tube; (3) By inclosing a soluble  $\text{Mg}$  salt with an alkaline-hydrogen carbonate, super-

saturating with  $\text{CO}_2$  in a strong vessel closed by a cork through which the  $\text{CO}_2$  can slowly escape (Senarmont, *C. R.* 28, 103); (4) By carefully heating  $\text{MgCO}_3 \cdot \text{KHCO}_3 \cdot 4\text{aq}$  to  $200^\circ$ , and extracting with water (Engel, *Bl.* [2] 44, 355). A white crystalline powder, isomorphous with aragonite by method (1); obtained in rhombohedra by (3); isodimorphous with  $\text{CaCO}_3$ . When moist it is alkaline to litmus.  $\text{CaSO}_4\text{Aq}$  partially decomposes it, especially in presence of  $\text{NaClAq}$  (Fleischer, *J. pr.* [2] 6, 273). Soluble in cold solutions of alkaline borates, ppd. on heating, but redissolved on cooling (Wittstein, *Ar. Ph.* [3] 6, 40). *Hydrates* (a)  $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ . Hexagonal prisms obtained by spontaneous evaporation of a solution of  $\text{MgCO}_3$  in excess of  $\text{CO}_2\text{Aq}$ . They lose water in dry air but retain their form. (b)  $\text{MgCO}_3 \cdot 5\text{H}_2\text{O}$ . Transparent oblique prismatic crystals obtained by exposure of above solution at a low temp. Converted into (a) by exposure to air &c. Boiled, they yield  $4\text{MgCO}_3 \cdot \text{MgH}_2\text{O}_2 \cdot 4\text{aq}$  (Fritzsche; v. also Engel, *C. R.* 101, 814).

**Hydrocarbonates.** As in the case of lead, the composition of pp. formed by adding an alkaline carbonate to solution of a  $\text{Mg}$  salt depends on proportions, strength, and temp. of solutions. A variable mixture of hydrocarbonates is known as *magnesia alba*; (a)  $4\text{MgCO}_3 \cdot \text{MgH}_2\text{O}_2 \cdot 4\text{aq}$ ; a white granular powder (for preparation v. Rose, *A.* 80, 231). (b)  $3\text{MgCO}_3 \cdot \text{Mg}(\text{HO})_2 \cdot 3\text{aq}$ , occurs native as *hydromagnesite* in small white monoclinic crystals (Dana). Prepared artificially (Berzelius, Fritzsche) it is a white, slightly soluble powder forming alkaline solutions. Dried at  $100^\circ$  in air it yields a (Rose). (c)  $3\text{MgO} \cdot 2\text{CO}_2 \cdot 3\text{aq}$  (?) (Fritzsche, *P.* 37, 310). Denied by Rose.

**Magnesium hydrogen carbonate.**  $\text{Mg} \cdot \text{H}_2(\text{CO}_3)_2$  (Soubeiran). Obtained by shaking up *magnesia alba* with  $\text{CO}_2\text{Aq}$ . The sol. has a bitter taste and alkaline reaction; becomes turbid at  $75^\circ$  but clears on cooling. Heated to  $50^\circ$ , or evaporated *in vacuo*, it yields hydrate a (v. supra) (Berzelius; Fritzsche).

**Magnesium-ammonium carbonate.**  $\text{Mg}(\text{NH}_4)_2(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$ . Translucent rhombohedra, from a mixture of cold  $\text{MgCl}_2\text{Aq}$ , or  $\text{MgSO}_4\text{Aq}$ , and  $\text{NH}_4$  sesquicarbonate solution.

**Magnesium-potassium carbonates:** (1)  $\text{Mg}(\text{KH})_2(\text{CO}_3)_2 \cdot 4\text{aq}$ . In large crystals from cold aqueous mixture of  $\text{MgCl}_2$  or  $\text{Mg}(\text{NO}_3)_2$  with excess of  $\text{KHCO}_3$ . The crystals at  $100^\circ$  become opaque, and lose water. Decomposed by water, leaving a residue  $6\text{MgCO}_3 \cdot \text{MgH}_2\text{O}_2 \cdot 6\text{aq}$  (Berzelius; also obtained in oblique rhombic prisms (Deville, *A. Ch.* 33, 75); (2)  $\text{Mg} \cdot \text{K}(\text{CO}_3)_2 \cdot 4\text{aq}$  by digesting *magnesia alba* at  $60^\circ$ – $70^\circ$  for 12 to 15 hours with  $\text{KHCO}_3\text{Aq}$  (Deville, *Lc.*).

**Magnesium-sodium carbonate**  $\text{MgNa}(\text{CO}_3)_2$ . Prepared in anhydrous microscopic crystals as the corresponding K salt.

On solubility of  $\text{MgCO}_3$  in  $\text{CO}_2\text{Aq}$  under pressure v. Merkel (*J.* 1867, 136) and Wagner (*J. pr.* 102, 233). On solubility of  $\text{MgCO}_3$  and  $\text{CaCO}_3$  in solutions of calcium and magnesium salts, and the reactions of dolomite or gypsum and magnesite in presence of water containing  $\text{CO}_2$  v. Hunt (*Am. S.* [2] 42, 49). For reactions of basic  $\text{MgCO}_3$  and gypsum with  $\text{CO}_2\text{Aq}$  v. Gossmann (*Am. S.* [2] 42, 217, 369).

**Manganese carbonate.**  $\text{MnCO}_3$ . S. water = 0.18; aqueous  $\text{CO}_2$  = 0.28 (John). Occurs native as *diallogite*, in rhombohedral crystals, isomorphous with calcite. Prepared by heating  $\text{MnCl}_2$  aq in sealed tubes to  $160^\circ$  with  $\text{Na}_2\text{CO}_3$  aq, or to  $140^\circ$ – $170^\circ$  with  $\text{CaCO}_3$  for 12 to 48 hours (Senarmont, *C. R.* 28, 693).  $2\text{MnCO}_3 \cdot \text{H}_2\text{O}$  is obtained by drying *in vacuo* the pp. formed by alkaline carbonates with manganous salts (*Gm.* 4, 214; Prior, *Tr.* 1869, 428). Dried in air pp. contains  $\text{Mn}_2\text{O}_3$ . Equivalent quantities of  $\text{Na}_2\text{CO}_3$  and  $\text{MnCl}_2$  yield  $5\text{MnCO}_3 \cdot 2\text{MnH}_2\text{O}_2$  (Rose, *A.* 80, 235).  $\text{MnCO}_3$  is a fine amorphous faintly rose-coloured powder. The hydrate is snow-white and tasteless. Anhydrous or hydrated the salt is permanent at ordinary temps. Heated to redness in air it yields  $\text{Mn}_2\text{O}_3$ . Strongly heated in H it yields  $\text{MnO}_2$ . In chlorine it gives  $4\text{MnCO}_3 + \text{Cl}_2 = \text{MnCl}_2 + \text{Mn}_2\text{O}_3 + 4\text{CO}_2$  (Wöhler). Chlorine water, or calcium hypochlorite solution, converts it first into  $\text{Mn}_2\text{O}_3$ , and then into  $\text{MnO}_2$ . Solutions of ammoniacal salts dissolve it when freshly ppd.

**Mercury carbonates.** *Mercuric carbonate* unknown. Neutral or acid carbonates of K or Na yield brown red pps.  $2\text{HgO} \cdot \text{HgCO}_3$  (Setterberg, *P.* 19, 60). Mercuric chloride yields an oxychloride.

**Mercurous carbonate.**  $\text{Hg}_2\text{CO}_3$ . A black or yellow powder.  $\text{Hg}_2\text{NO}_3$  aq is mixed with slight excess of  $\text{Na(ork)HCO}_3$  aq; the mixture is set aside for a few days and frequently stirred, and the pp. then washed quickly, and dried over  $\text{H}_2\text{SO}_4$  *in vacuo* (Setterberg, *loc. cit.*). Easily loses  $\text{CO}_2$ ; is converted into  $\text{HgO}$  by exposure to air; blackened by alkalis with separation of Hg (*Gm.* 6, 15).

**Nickel carbonate.**  $\text{NiCO}_3$ . For preparation, v. COBALT CARBONATE. It is a greenish-white powder in minute rhombohedra scarcely attacked by strong acids at ordinary temperatures.

#### Hydrate carbonates:

(1)  $\text{NiCO}_3 \cdot 2\text{NiH}_2\text{O} \cdot 4\text{H}_2\text{O}$ . Occurs native as *emerald nickel* (Silliman, *Am. S.* [2] 6, 218; Shepard, *ibid.* 250). (2)  $2\text{NiCO}_3 \cdot 3\text{NiH}_2\text{O} \cdot 4\text{H}_2\text{O}$  is the pp. obtained from cold  $\text{NiSO}_4$  aq and  $\text{Na}_2\text{CO}_3$  aq, when dried at  $100^\circ$ . Boiled with water takes up water and loses  $\text{CO}_2$ . Heated above  $100^\circ$  in air gives off water and  $\text{CO}_2$ , and is partly converted into  $\text{Ni}_2\text{O}_3$  (Rose, *A.* 80, 237). Not altered by digestion at  $60^\circ$ – $70^\circ$  with  $\text{NaHCO}_3$  aq (Deville). The pps. produced by alkaline carbonates in solutions of nickel salts vary with temperature, strength, and proportions, of solutions employed.

#### Nickel-potassium carbonates:

(1)  $\text{NiK}_2(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$ ; shining apple-green microscopic needles. (2)  $\text{NiKH}(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$ : light-green, apparently oblique rhombic prisms. Obtained similarly to corresponding cobalt salts (Deville).

**Nickel-sodium carbonate.**  $\text{NiNa}(\text{CO}_3)_2 \cdot 10\text{H}_2\text{O}$  is obtained like the cobalt salt, in small prisms (Deville).

**Palladium carbonate.** A light yellow pp. is formed by adding solution of an alkaline carbonate to a solution of a Pd salt. No  $\text{CO}_2$  is evolved at first, but on continuing ppn. effervescence ensues and pp. turns brown. A small quantity of  $\text{CO}_2$  retained when dry (Berzelius).

**Potassium carbonates.** Two salts have been obtained.

**I. Normal carbonate:**  $\text{K}_2\text{CO}_3$ . S. 95.2 at  $3^\circ$ ; 111 at  $12^\circ$ ; 204 at  $70^\circ$ . The commercial salt is prepared by treating the ash of plants, especially of beetroot, with water, and evaporating. The residue, containing 60–80 p.c.  $\text{K}_2\text{CO}_3$ , is sold as '*rude potash*.' The impurities— $\text{KCl}$ ,  $\text{K}_2\text{SO}_4$ , and a little  $\text{K}$  silicate—are partially removed by digesting for several days with its own weight of cold water, decanting, and evaporating quickly with constant stirring. The small crystals obtained are washed with pure  $\text{K}_2\text{CO}_3$  aq, dried, and heated to redness in metal vessels; the product is '*pearl ash*,' which usually contains from 2 to 3 p.c. impurities.

Pure  $\text{K}_2\text{CO}_3$  is prepared (1) by heating pure K oxalate; (2) by digesting powdered cream of tartar with water containing a little  $\text{HCl}$ , washing, drying to render silica insoluble, crystallising from water to remove Na salts, heating in a closed silver dish, digesting residue with hot water, filtering, evaporating to dryness, dissolving in cold water, evaporating, and repeating treatment with cold water and evaporation two or three times (Stas, *Chem. Propri.* 340). (v. also Smith, *C. N.* 30, 234).

**Properties and Reactions.**—White solid, melting at red heat ( $83^\circ$ ) (Carnelley, *C. J.* 33, 280), volatilisised without change at white heat; very deliquescent;  $[\text{K}^+\text{CO}_3\text{Aq}] = 6490$  (*Tk.* 3, 198). Solution strongly alkaline; hot solution deposits rhombic octahedral  $\text{K}_2\text{CO}_3 \cdot 2\text{H}_2\text{O}$ ; conc. solution deposits monoclinic crystals  $2\text{K}_2\text{CO}_3 \cdot 3\text{H}_2\text{O}$ , which at  $100^\circ$  give  $\text{K}_2\text{CO}_3 \cdot \text{H}_2\text{O}$  (Städeler, *A.* 133, 371; Pohl, *W. A. B.* 41, 630). Heated with aqueous vapour is partly decomposed, giving  $\text{KOH}$ ; heated with charcoal gives K and CO (v. POTASSIUM); heated with sulphur forms K sulphide and sulphate, and  $\text{CO}_2$  (Berthelot, *B.* [2] 40, 362); heated in sulphur dioxide gives  $\text{K}_2\text{SO}_4$  and traces of  $\text{K}_2\text{S}$  (Berthelot, *A.* [2] [5] 30, 547). Solutions, about 1 in 10  $\text{H}_2\text{O}$ , partly decomposed by  $\text{CaO}_2 \cdot \text{H}_2\text{O}$ , giving  $\text{KOH}$  aq; amount of change much increased by boiling; reverse reaction occurs with more conc. solutions.

**II. Potassium-hydrogen carbonate:**  $\text{KHCO}_3$ . S. 22.4 at  $0^\circ$ ; 33.2 at  $20^\circ$ ; 45.2 at  $40^\circ$ ; 16.4 at  $60^\circ$  (Dibbitts, *J. pr.* [2] 10, 417). Prepared (1) by passing  $\text{CO}_2$  into solution of commercial normal carbonate; (2) by passing  $\text{CO}_2$  into solution obtained by lixiviating residue from heating K-I tartrate in closed vessels, and crystallising. **Properties and Reactions.**—Large transparent monoclinic crystals,  $\text{KHCO}_3 \cdot \text{H}_2\text{O}$ ; solution has slightly alkaline reaction, and gives off  $\text{CO}_2$  on gently warming (v. Dibbitts, *J. pr.* [2] 10, 417). At  $200^\circ$  gives  $\text{K}_2\text{CO}_3$  and  $\text{CO}_2$ .

**Rubidium carbonate**  $\text{Rb}_2\text{CO}_3$ . By ppn. of  $\text{Rb}_2\text{SO}_4$  aq with  $\text{BaO}$  aq, adding  $(\text{NH}_4)_2\text{CO}_3$  to filtrate, evaporating to dryness, exhausting with water, and evaporating this solution, indistinct crystals of  $\text{Rb}_2\text{CO}_3 \cdot \text{H}_2\text{O}$  are obtained. Soluble in alcohol, strongly alkaline. Heated, loses water and leave  $\text{Rb}_2\text{CO}_3$  as a sandy powder, which melts at a higher temperature. In air it deliquesces, and yields  $\text{RbHCO}_3$  in glassy prismatic crystals; permanent in air; having very faint alkaline reaction; easily converted by heat

into  $\text{Bb}_2\text{CO}_3$  (Bunsen & Kirchhoff) (melting-point,  $337^\circ$ ; Carnelley & A. Williams, *C. J.* 37, 125).

**Samarium carbonate.**  $\text{Sm}_2(\text{CO}_3)_3 \cdot 3\text{H}_2\text{O}$ . Needles insoluble in water. The following double salts have also been prepared. *Samarium-ammonium carbonate*,  $\text{SmNH}_4(\text{CO}_3)_2 \cdot 2\text{H}_2\text{O}$ . *Samarium-potassium carbonate*,  $\text{SmK}(\text{CO}_3)_2 \cdot 6\text{H}_2\text{O}$ ; brilliant needles. *Samarium-sodium carbonate*,  $\text{SmNa}(\text{CO}_3)_2 \cdot 8\text{H}_2\text{O}$ ; a crystalline pp. (Clève, *Bl.* [2] 43, 168).

**Silver carbonate**  $\text{Ag}_2\text{CO}_3$ . Prepared in crystals by adding ammonia by drops to mixed solutions of  $\text{AgNO}_3$  and  $\text{Na}_2\text{CO}_3$  of definite strength (Vögel, *J. pr.* 87, 288). As a white pp., becoming yellow on washing, by adding  $\text{Na}_2\text{CO}_3$  aq. to  $\text{AgNO}_3$  aq. Blackens on exposure to light. Is readily soluble in strong  $\text{NH}_4$  aq. Solution treated with absolute alcohol yields a pp. containing  $\text{Ag}_2\text{CO}_3$  and ammonia (Berzelius). At  $200^\circ$  loses  $\text{CO}_2$  and leaves  $\text{Ag}_2\text{O}$ . By ppg.  $\text{AgNO}_3$  aq. with large excess of alkaline carbonate and boiling, a substance, possibly a mixture, is obtained which dried at  $100^\circ$  has formula  $\text{Ag}_2\text{CO}_3 \cdot 2\text{Ag}_2\text{O}$  (Rose, *A.* 61, 202). *Ammonio-silver carbonate*  $\text{Ag}_2\text{CO}_3 \cdot 4\text{NH}_3$ . A grey pp. on adding absolute alcohol to  $\text{Ag}_2\text{CO}_3$  dissolved in  $\text{NH}_4$  aq. (Keen, *C. N.* 31, 231).

**Sodium carbonates.** Three salts have been isolated, besides various hydrates, and several double salts.

I. *Normal carbonate*  $\text{Na}_2\text{CO}_3$ . Occurs in waters of several lakes and mineral waters; is a constant constituent of ash of sea-plants.

**Formation.**—1. From  $\text{Na}_2\text{SO}_4$  by heating with C and  $\text{CaCO}_3$ , and lixiviating with  $\text{H}_2\text{O}$  (Leblanc's process).—2. From cryolite, by heating with CaO and decomposing the Na aluminate formed by  $\text{CO}_2$ .—3. By reaction between NaCl and  $(\text{NH}_4)_2\text{CO}_3$  in solution.

**Preparation.**—1. Soda crystals are repeatedly washed with cold water until all sulphates, chlorides, &c. are removed; the last traces of  $\text{SiO}_2$  are removed by dissolving the washed salt in water, evaporating nearly to dryness, adding a little  $(\text{NH}_4)_2\text{CO}_3$ , heating till quite dry, dissolving in water, filtering, evaporating, and heating (Wurtz, *J.* 1853, 357).—2. Soda crystals are repeatedly recrystallised, the crystals being obtained as small as possible (Gay-Lussac, *A.* 12, 15); most of the chlorides and sulphates and iron salts are thus removed. The washed salt is dried, heated in a silver dish, and the residue is repeatedly washed with small quantities of cold water; the salt is now free from iron, but may contain traces of silica (*v. supra*) (Stas).

**Properties and Reactions.**—White solid; melts at  $818^\circ$  (Carnelley, *C. J.* 33, 280), giving off a little  $\text{CO}_2$  (Jacquelin, *A. Ch.* [3] 32, 205; Mallard, *A. Ch.* [4] 28, 86; Scheerer, *A.* 116, 134). Heated in steam gives NaOH. Decomposed at high temperature by carbon, to Na and CO; by phosphorus, to C, CO, and Na orthophosphate (Dragendorff, *C. C.* 1861, 865); by silicon to C, CO, and Na silicate; by sulphur, at  $275^\circ$ , to  $\text{Na}_2\text{S}$  and  $\text{Na}_2\text{S}_2\text{O}_3$ , at melting-point, to  $\text{Na}_2\text{S}$  and  $\text{Na}_2\text{SO}_3$ ; by ferric oxide, or ferric oxide, with evolution of  $\text{CO}_2$  (Stromeyer, *A.* 107, 866); by ferrous sulphide to Na and Na-Fe sulphide (E. Kopp, *Bl.* [2] 5, 207). Solubility

in water increases from  $0^\circ$  to  $34^\circ$ ; from  $34^\circ$  to  $79^\circ$  *S.* is constant: *S.* = 46.2 at  $34^\circ$  (Löwel, *A. Ch.* [3] 33, 353; Poggiale, *A. Ch.* [3] 8, 468; Tomlinson, *C. N.* 18, 2; Gerlach, *Fr.* 8, 279). Solution is accompanied with production of heat;  $[\text{Na}^+\text{CO}_3^-\text{Aq}] = 5,640$  (*Th.* 3, 198).

**Hydrates of  $\text{Na}_2\text{CO}_3$ .**—(1)  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ ; separates from moderately conc. solutions at ordinary temperatures, in clear, monoclinic crystals; these melt at c.  $34^\circ$ , leaving  $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$  (Schindler, *Mag. Pharm.* 33, 14); according to Thomsen (*B.* 11, 2012) the residue is  $\text{Na}_2\text{CO}_3 \cdot 2\text{H}_2\text{O}$  but this gives up another  $\text{H}_2\text{O}$  in the air. Crystals of  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  effloresce in air; at  $12.5^\circ$  they give the hydrate with  $5\text{H}_2\text{O}$ ; and at  $38^\circ$  in *vacuo*, or over  $\text{CaCl}_2$ , the hydrate  $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$  (Watson, *I. M.* 12, 130). Dissolve in water with disappearance of heat  $[\text{Na}^+\text{CO}_3^-\text{H}_2\text{O} \cdot \text{Aq}] = -16,160$  (*Th.* 3, 198).

(2)  $\text{Na}_2\text{CO}_3 \cdot 15\text{H}_2\text{O}$  (Jacquelin, *A. Ch.* [3] 32, 205). Crystallises from conc. solutions of  $\text{Na}_2\text{CO}_3$  at  $-20^\circ$ .

(3)  $\text{Na}_2\text{CO}_3 \cdot 7\text{H}_2\text{O}$  (Löwel, *A. Ch.* [3] 33, 353; Rammelsberg; Marignac, *Ann. M.* [5] 12, 55). Crystallises from hot saturated solutions by cooling in closed vessels; if air has entrance the  $10\text{H}_2\text{O}$  hydrate forms. Said to crystallise in two modifications, rhombohedra and rhombic tables, with different solubilities.

(4)  $\text{Na}_2\text{CO}_3 \cdot 6\text{H}_2\text{O}$ ; crystallises from  $\text{Na}_2\text{SAq}$  standing in air, also from  $\text{NaClAq}$  mixed with  $\text{K}_2\text{CO}_3$  aq. (Mitscherlich, *P.* 8, 441).

(5)  $\text{Na}_2\text{CO}_3 \cdot 5\text{H}_2\text{O}$ ; crystallises at temperatures over  $33^\circ$  from molten  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  (Berzelius, *P.* 32, 363); also by the efflorescence of  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  at  $12.5^\circ$ .

(6)  $\text{Na}_2\text{CO}_3 \cdot 2\text{H}_2\text{O}$ ; melting  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  at  $34^\circ$  (Thomsen);  $[\text{Na}^+\text{CO}_3^-\text{H}_2\text{O} \cdot \text{Aq}] = 20$ .

(7)  $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$ ; from hot saturated solutions of  $\text{Na}_2\text{CO}_3$ , or from hot solutions of  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ ; separates from boiling solutions; also produced by efflorescence of some of the hydrates with more  $\text{H}_2\text{O}$  (Marignac, *Ann. M.* [5] 12, 55; Haidinger, *A.* 5, 369).  $[\text{Na}^+\text{CO}_3^-\text{H}_2\text{O} \cdot \text{Aq}] = 2,250$  (*Th.*).

II. *Sodium-hydrogen carbonate*;  $\text{NaHCO}_3$  (*Bicarbonate of soda*). **Formation.**—1. By passing  $\text{NH}_3$  into  $\text{NaClAq}$ , and then decomposing by  $\text{CO}_2$  under pressure;

$\text{NH}_3 + \text{NaClAq} + \text{CO}_2 + \text{H}_2\text{O} = \text{NaHCO}_3 + \text{NH}_4\text{ClAq}$  (Ammonia-soda process).—2. By reaction between soda crystals in solution and commercial  $\text{NH}_3$  carbonate.—3. By reaction between  $\text{CO}_2$  and effloresced soda crystals, or a mixture of 2 parts crystallised and 3 parts dry  $\text{Na}_2\text{CO}_3$ .—4. By passing  $\text{CO}_2$  into  $\text{Na}_2\text{CO}_3$  aq. as long as it is absorbed (1 part  $\text{Na}_2\text{CO}_3$  in 2 parts  $\text{H}_2\text{O}$ ) (L. Meyer, *A. Suppl.* 2, 170; Berzelius, *P.* 16, 134; Mohr, *A.* 19, 15; 29, 268).

**Properties and Reactions.**—White monoclinic tables; alkaline taste; changes moist litmus to blue, but has no action on colour of turmeric paper. In moist air readily goes to  $\text{Na}_2\text{CO}_3$  aq. When heated gives off  $\text{CO}_2$  and  $\text{H}_2\text{O}$ ; solution decomposed on boiling (Rose, *P.* 34, 158). *S.* 8.8 at  $10^\circ$ ; 14.64 at  $70^\circ$  (Poggiale, *A. Ch.* [3] 8, 468; also Dibbitts, *J. pr.* [2] 10, 417).

III. *Sesquicarbonate*.  $\text{Na}_2\text{H}_2(\text{CO}_3)_3 \cdot 3\text{H}_2\text{O}$  ( $= \text{Na}_2\text{CO}_3 \cdot 2\text{NaHCO}_3 \cdot 3\text{H}_2\text{O}$ ). Occurs native; *S.G.* 2.112. Prepared (1) by heating  $\text{NaHCO}_3$  to  $200^\circ$  (Hermann, *J. pr.* 26, 312); (2) by exapo-

rating solutions of  $\text{NaHCO}_3$  in *vacuo* over  $\text{H}_2\text{SO}_4$ ; (3) by melting together the two carbonates, in the ratio  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O} : 2\text{NaHCO}_3$ , and standing in air till mass becomes crystalline, when it contains crystals of the sesquicarbonate; (4) by pouring alcohol on to a mixture of  $\text{Na}_2\text{CO}_3\text{Aq}$  and  $\text{NaHCO}_3$ , the salt separates in fine needles (Winkler, *Z. P.* 48, 215). Monoclinic crystals; non-efflorescent in air, goes to  $\text{Na}_2\text{CO}_3$  at red heat; aqueous solution in *vacuo* over  $\text{H}_2\text{SO}_4$  gives  $\text{Na}_2\text{CO}_3$  and  $\text{NaHCO}_3$  (Rose, *P.* 34, 160). S.  $12.63$  at  $0^\circ$ ;  $41.59$  at  $100^\circ$  (Poggiale).

IV. Double Salts. Sodium-potassium carbonates.

(1)  $\text{NaKCO}_3 \cdot 6\text{H}_2\text{O}$ ; monoclinic crystals, unchanged in dry air, effloresces in moist air; by evaporating solution of equal equivalents of the constituent salts, and crystallising from  $\text{K}_2\text{CO}_3\text{Aq}$ . At  $100^\circ$  loses  $6\text{H}_2\text{O}$ . S.  $185$  at  $15^\circ$  (Marignac, *C. R.* 45, 650; Marguerite, *A.* 56, 220; Stolba, *Bl.* [2] 4, 192, 7, 241).

(2)  $2\text{Na}_2\text{CO}_3 \cdot \text{K}_2\text{CO}_3 \cdot 18\text{H}_2\text{O}$ ; from mother-liquor from which  $\text{K}_4\text{Fe(CN)}_6$  has crystallised out. May be crystallised from  $\text{K}_2\text{CO}_3\text{Aq}$  (Marguerite).

SODIUM-CALCIUM CARBONATE:

$\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$ ; occurs native as *Gay-Lussite*; obtained, in microscopic monoclinic crystals, by reaction between freshly *ppd.*  $\text{CaCO}_3$  and conc.  $\text{Na}_2\text{CO}_3\text{Aq}$  at ordinary temperature. When dry this compound is decomposed by water (Fritzsche, *J. pr.* 93, 339; Boussingault, *P.* 7, 97; H. Rose, *P.* 93, 606).

**Strontium carbonate.**  $\text{SrCO}_3$ . S.G. (*pp.*) =  $3.62$ . S. (cold or *had*) =  $.0003$  (Bineau, *G. R.* 41, 509). S. (cold) =  $.005$  (Fresenius) solubility diminished by  $\text{NH}_4\text{Aq}$  or  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ . S. ( $10^\circ$  in satd.  $\text{CO}_2\text{Aq}$ ) =  $.12$  (Lassaigne). Occurs native as *strontianite*. Crystals of trimetric system, isomorphous with aragonite and witherite. Prepared by *ppn.* with an alkaline carbonate as a smooth white substance; in form of *strontianite*, by crystallising amorphous carbonate from fused  $\text{KCl}$  and  $\text{NaCl}$  (Bottger, *Bl.* [2] 37, 417). Heated in closed vessel  $\text{CO}_2$  given off only at about white heat, but in aqueous vapour  $\text{SrH}_2\text{O}_2$  is formed at a much lower temp. Alkaline sulphates in solution do not decompose it at any temperature (Rose, *P.* 95, 284). Ammonium chloride solution boiled with it converts it into  $\text{SrCl}_2$ .

**Thallium carbonate**  $\text{Tl}_2\text{CO}_3$ . S.G. (fused)  $7.06$  (Lamy). S. ( $15.5^\circ$ ) =  $4.02$ ; ( $60^\circ$ ) =  $11.7$ ; ( $100^\circ$ ) =  $27.21$ . M.P. c.  $272^\circ$  (Carmelley, *C. J.* 33, 275). Formed by exposure of  $\text{Tl}$  in a saturated solution of  $\text{Tl}_2\text{O}$  to air. Prepared by allowing granulated metal to oxidise in warm air, boiling with water containing excess  $(\text{NH}_4)_2\text{CO}_3$  and filtering.  $\text{Tl}_2\text{CO}_3$  is deposited in groups of prisms (Miller, *Pr.* 14, 555), which are brilliant, highly refractive, very heavy, anhydrous, colourless; melting, undecomposed, much below redness to clear liquid which solidifies to dark-grey mass, and at red heat decomposes evolving  $\text{CO}_2$ . Taste mildly caustic and metallic. Solution has alkaline reaction, not completely removed by super-saturation with  $\text{CO}_2$  (Cooke; Werther, *J.* 1864, 249).

**Thorium carbonate.**  $\text{Th}(\text{CO}_3)_3 \cdot 3\text{ThH}_2\text{O} \cdot 2\text{H}_2\text{O}$ . Alkaline carbonates throw down a basic salt with evolution of  $\text{CO}_2$ . Moist  $\text{ThH}_2\text{O}$  absorbs  $\text{CO}_2$  from air.  $\text{ThO}_2$  is not sol. in water containing  $\text{CO}_2$  (Berzelius). Salt of above formula obtained

as an amorphous *pp.* by treating hydrate suspended in water with  $\text{CO}_2$ , or by *ppg.* solution of  $\text{ThCl}_4$  with an alkaline carbonate.

**Tin carbonates.**  $\text{SnCO}_3$ ,  $\text{SnO}$ ; by adding solid  $\text{SnCl}_4$  to conc.  $\text{Na}_2\text{CO}_3\text{Aq}$  in absence of air: very unstable. If  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  is used, hexagonal prisms of  $(\text{NH}_4)_2\text{O} \cdot 2\text{SnO} \cdot 3\text{CO}_2 \cdot 3\text{H}_2\text{O}$  are said to be formed (Deville, *A. Ch.* [3] 35, 448).

Uranium carbonates have not been isolated. Alkaline carbonates ppt. uranous hydrate from  $\text{UCl}_4$ , a basic sulphate from  $\text{U}(\text{SO}_4)_2$ , and double carbonates from uranic salts.

**Urenyl-ammonium carbonate.**

$(\text{UO}_2)_2\text{CO}_3 \cdot 2(\text{NH}_4)_2\text{CO}_3$ . S. =  $5$  at  $15^\circ$ ; increased by  $(\text{NH}_4)_2\text{CO}_3$ . Prepared, in small yellow transparent crystals, by digesting in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  at  $60^\circ$ - $80^\circ$  the *pp.* produced by  $\text{NH}_4\text{Aq}$  or  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  from uranic salts, filtering, and allowing to cool. Decomposed slowly at ordinary, more quickly at higher, temps. leaving  $\text{UO}_2$ ; solution boiled evolves  $\text{NH}_3$  and  $\text{CO}_2$ , and deposits yellow *pp.*, containing uranium, of doubtful composition (Arfredson, Pélégot; Ebelmen, *A. Ch.* [3] 5, 189; Delffs, *P.* 55, 229).

**Urenyl-potassium carbonate.**

$(\text{UO}_2)_2\text{CO}_3 \cdot 2\text{K}_2\text{CO}_3$ . S. =  $7.4$  at  $15^\circ$ ; insol. in alcohol. Prepared, as a bright yellow crystalline crust, by dissolving in  $\text{KHCO}_3\text{Aq}$  the *pp.* formed from uranic salts by  $\text{K}_2\text{CO}_3\text{Aq}$ , and evaporating. At  $300^\circ$  evolves  $\text{CO}_2$ ; at red heat leaves mixture of K uranate and carbonate.  $\text{KOH}\text{Aq}$  *pps.* all the U as K uranate, even in presence of excess of  $\text{K}_2\text{CO}_3$ .

**Urenyl-sodium carbonate.**

$(\text{UO}_2)_2\text{CO}_3 \cdot 2\text{Na}_2\text{CO}_3$ . Preparation and properties similar to K salt. Two Ca salts,

(1)  $(\text{UO}_2)_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 10\text{H}_2\text{O}$ ;

(2)  $(\text{UO}_2)_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$ ;

occur native (Smith, *A.* 66, 253).

**Yttrium carbonate.**  $\text{Y}_2(\text{CO}_3)_3$ .  $\text{Na}_2\text{CO}_3\text{Aq}$  *pps.* it from yttrium salts with  $12\text{H}_2\text{O}$  in the cold, and  $\text{H}_2\text{O}$  at  $100^\circ$ . Not easily decomposed by heat; sparingly soluble in water containing  $\text{CO}_2$ . Solution in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ , if concentrated, deposits a white crystalline double salt which does not redissolve in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ ; also soluble in  $\text{K}_2\text{CO}_3$  and  $\text{Na}_2\text{CO}_3\text{Aq}$  (Berzelius).

**Zinc carbonate.**  $\text{ZnCO}_3$ . Occurs as *calamine*. Not obtained by precipitation. *Pp.* formed by  $\text{KHCO}_3\text{Aq}$  in  $\text{ZnSO}_4\text{Aq}$  is  $2\text{ZnCO}_3 \cdot 3\text{ZnO} \cdot \text{H}_2\text{O}$  (Berzelius).  $\text{ZnCO}_3$  unaltered at  $200^\circ$ ; slowly evolves  $\text{CO}_2$  at  $300^\circ$  (Rose).

**Hydrocarbonates.** Native hydrocarbonates are (1) *zinc bloom*  $\text{ZnO} \cdot \text{ZnCO}_3 \cdot 3\text{ZnH}_2\text{O}_2$  (Berzelius), or  $\text{ZnCO}_3 \cdot 2\text{ZnH}_2\text{O}_2\text{Aq}$  (Smithson *A. Borndorff, Gm.* 6, 15). (2) *Auriscalite* or *green calamine*  $2\text{ZnCO}_3 \cdot 3\text{ZnH}_2\text{O}_2$ , in which Zn is partly replaced by Cu. (3) *Durait*, a hydrocarbonate containing Cu and Ca.

The *pps.* formed by alkaline carbonates in solutions of zinc salts all appear to contain water, and to vary in composition with strength, temperature, and proportions, of solutions. For results obtained under varying conditions, v. Rose (*P.* 85, 107), Schindler & Boussingault (*Gm.* 1, 15). They all evolve  $\text{CO}_2$  and  $\text{H}_2\text{O}$  at  $200^\circ$ , yielding  $\text{ZnO}$  (Rose).

**Ammonio-carbonate of zinc**  $(\text{NH}_4)_2\text{ZnCO}_3$ .

Deposited in crystals from a solution of *ppd.* zinc carbonate in conc.  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  (Favre, *Traité de Chimie*, Pelouze et Frémy, 2nd ed. 8, 47).

**Zinc-potassium carbonate**  $8\text{ZnCO}_3 \cdot 3\text{K}_2\text{CO}_3 \cdot 7\text{H}_2\text{O}$  (?). Crystallises from a solution of  $\text{ZnCl}_2$  mixed with K sesquicarbonate (Dewille, *A. Ch.* [3] 32, 75).

**Zinc and sodium carbonate**  $8\text{ZnCO}_3 \cdot 3\text{Na}_2\text{CO}_3$  (?). Small crystals, obtained as potassium salt (Dewille).

**Zirconium carbonate**. Excess of alkaline carbonate solution produces a ppt. in solutions of Zr salts, soluble in  $\text{Na}_2\text{O}(\text{or K})\text{CO}_3\text{Aq}$ . Composition seems to be variable (Hermann, Klaproth, Vauquelin).

**THIO-CARBONIC ACID**.  $\text{H}_2\text{CS}_3$ . Mol. w. unknown. A dark yellow very strongly smelling oil; obtained by adding cold dilute  $\text{HClAq}$  to  $\text{K}_2\text{CS}_3$  or  $\text{Na}_2\text{CS}_3$ ; very easily decomposed, by heating, to  $\text{CS}_2$  and  $\text{H}_2\text{S}$  (Zeise, *S.* 41, 105; Berzelius, *P.* 6, 450).

**THIO-CARBONATES**. These salts have the composition  $\text{M}_2\text{CS}_3$ , or  $\text{MCS}_3$ , when  $\text{M}_2 = \text{Na}_2$  &c., and  $\text{M} = \text{Ca}$  &c. A few basic salts are also known. The composition of the salts of the alkali and alkaline earth metals has been determined; several other thio-carbonates seem to be produced in the reactions between solutions of metallic salts and  $\text{K}_2\text{CS}_3\text{Aq}$  or  $\text{Na}_2\text{CS}_3\text{Aq}$ , but the composition of very few of these thio-carbonates of the heavy metals has been determined. Thio-carbonates are formed by reactions between  $\text{CS}_2$  and aqueous solutions of the monosulphides of the alkali and alkaline earth metals,  $\text{M}_2\text{S}$  and  $\text{MS}$ . By using  $\text{MOHAq}$  and  $\text{CS}_2$ , thio-carbonates and carbonates are formed simultaneously; with  $\text{MO}_2\text{HAq}$  and  $\text{CS}_2$ , ( $\text{M} = \text{Ca, Ba, Sr}$ ) basic thio-carbonates are formed, e.g.  $\text{CaCS}_3 \cdot 2\text{CaO} \cdot \text{H}_2\text{O}$ .  $\text{NH}_3\text{Aq}$  reacts with  $\text{CS}_2$  to form  $(\text{NH}_4)_2\text{CS}_3$  and  $(\text{NH}_4)_2\text{CNS}$  (Gélin, *J.* 1861, 340). The thio-carbonates are yellow, red-yellow, brown, or black, solids; the hydrated salts are yellow. The salts of the alkali and alkaline earth metals are soluble in water; those of the heavy metals are more or less soluble in excess of  $\text{M}_2\text{CS}_3\text{Aq}$  ( $\text{M} = \text{Na}$  &c.). The thio-carbonates are not very stable; those of the heavy metals easily decompose to metallic sulphide and  $\text{CS}_2$ ; conc. solutions of the alkali salts change to  $\text{H}_2\text{S}$  and alkali carbonates when boiled, dilute solutions decompose by standing in air to carbonates and S. Heated alone, most of them give metallic sulphide and  $\text{CS}_2$ ;  $\text{K}_2\text{CS}_3$  gives  $\text{K}_2\text{S}$  and C. The thio-carbonates have been chiefly investigated by Zeise (*S.* 41, 105); Berzelius (*P.* 6, 450); Walker (*C. N.* 30, 28); Sestini (*G.* 1871, 473; *B.* 5, 327); Gélin (*J. Ph.* [3] 39, 95; *C. R.* 81, 282); P. Thénard (*C. R.* 79, 673); Husemann (*A.* 123, 67); Mermet (*C. R.* 81, 344).

**Ammonium thiocarbonate**  $(\text{NH}_4)_2\text{CS}_3$ . Prepared by fixing a saturated alcoholic solution of  $\text{NH}_3$  with its vol.  $\text{CS}_2$ , cooling after the liquid has become brown, pouring off liquid, and washing the crystals several times with alcohol, then with ether, and pressing between paper (Zeise). Yellow crystals, v. sol. in water, insol. in alcohol or ether; may be sublimed in dry air by gentle warming; very hygroscopic. Aqueous solution heated to  $90^\circ\text{--}100^\circ$  evolves  $\text{H}_2\text{S}$ , and  $\text{NH}_4\text{CNSAq}$  remains (Gélin).

**Barium thiocarbonate**  $\text{BaCS}_3$ . By shaking  $\text{BaSAq}$  with  $\text{CS}_2$ , washing with alcohol, and drying *in vacuo*.

**Calcium thiocarbonate**,  $\text{CaCS}_3$ . By digesting  $\text{CaS}$  with excess of  $\text{CS}_2$ , and evaporating *in vacuo*. Citron-yellow; sol. in alcohol or water; milk of lime shaken with  $\text{CS}_2$  gives an orange-red ppt. of  $\text{CaCS}_3 \cdot 2\text{CaO} \cdot \text{H}_2\text{O}$ , and this at  $30^\circ$  gives red liquid from which red crystals of  $\text{CaCS}_3 \cdot 3\text{CaO} \cdot \text{H}_2\text{O}$  separate (Walker; Sestini).

**Potassium thiocarbonate**,  $\text{K}_2\text{CS}_3$ . When  $\text{K}_2\text{SAq}$  is digested with  $\text{CS}_2$  at  $30^\circ$  in a closed vessel, or  $\text{CS}_2$  is dissolved in a conc. alcoholic solution of  $\text{K}_2\text{S}$ , yellow deliquescent crystals separate; dried at  $60^\circ\text{--}80^\circ$  these give  $\text{K}_2\text{CS}_3$ , a red-brown solid; v. sol. in water, al. sol. in alcohol.

The other thiocarbonates which have been fairly well examined and analysed are those of Lithium, Magnesium, Sodium, and Strontium. Thiocarbonates of Bi, Cd, Cr, Co, Au, Fe, Pb, Mn, Hg, Ni, Pt, Ag, Sn, Zn, seem also to be formed by adding the solution of an alkali thiocarbonate to a solution of a salt of each of these metals. M. M. P. M.

**CARBONIC ANHYDRIDE**  $\text{CO}_2$  v. CARBON, OXIDES OF.

**CARBON TETRA-CHLORIDE** v. *supra* and TETRA-CHLORO-METHANE.

**CARBONIC ETHERS**. There are three classes of carbonic ethers: viz. acid ethers  $\text{CO}(\text{OR})(\text{OH})$ , normal ethers  $\text{CO}(\text{OR})_2$ , and ethers of ortho-carbonic acid  $\text{C}(\text{OR})_4$ . In these formulae R may be any alkyl. They are described as salts of the alkyl: e.g. ETHYL CARBONATE, METHYL CARBONATE, PHENYL CARBONATE, &c.

Orthocarbonic ethers are formed by the action of sodium alcohols on chloropierin (Williamson a. Bassett, *A.* 132, 54). They are converted by ammonia into guanidine.

**Normal carbonic ethers**.

**Formation**.—1. From alkyl iodides and silver carbonate (de Clermont, *A.* 91, 375).—2. By the action of  $\text{Na}$ ,  $\text{K}$ , solid  $\text{NaOEt}$  (4 mol.) or  $\text{KOEt}$  (4 mol.), upon alkyl oxalates (1 mol.) (Etting, *A.* 19, 17; Löwig a. Weidmann, *A.* 436, 301; Geuther, *Z.* 1868, 656; Craunston a. Dittmar, *Z.* 1870, 4).—3. By the action of alkyl chloroformates upon sodium alcohols, e.g.:

$\text{Cl.CO.OEt} + \text{NaOMe} = \text{NaCl} + \text{Me.CO.OEt}$  (Roese, *A.* 205, 240). The mixed ether prepared from ethyl chloroformate and sodium methylate is identical with that from methyl chloroformate and sodium ethylate.—4. From  $\text{COCl}_2$  and sodium alcohols.

**Properties**.—The boiling-points and specific gravities of the fatty carbonic ethers are as follows (Roese, *A.* 205, 244):—

Ether	Boiling-point	S.G.
$\text{Me}_2\text{CO}$	$90.6^\circ$	1.055 at $17^\circ$
$\text{MeEtCO}$	$109.2^\circ$	1.00 at $27^\circ$
$\text{Et}_2\text{CO}$	$125^\circ$	.97
$\text{MePrCO}$	$139.8^\circ$	.98 at $27^\circ$
$\text{Pr}_2\text{CO}$	$157.2^\circ$	.95 at $17^\circ$
$\text{Me}(\text{PrCH}_2)_2\text{CO}$	$143.6^\circ$	.95 at $27^\circ$
$\text{Et}(\text{PrCH}_2)_2\text{CO}$	$160.1^\circ$	.93 at $27^\circ$
$(\text{PrCH}_2)_3\text{CO}$	$190.3^\circ$	.92 at $15^\circ$
$\text{Et}(\text{C}_4\text{H}_9)_2\text{CO}$	$182.3^\circ$	.92 at $27^\circ$
$(\text{C}_4\text{H}_9)_3\text{CO}$	$228.7^\circ$	.91 at $15^\circ$

**Reactions.**—1. Ammonia converts the ethers  $R_2CO_2$  into carbamic ethers, and finally into urea.—2.  $PCl_5$  forms chloroformic ethers. In mixed ethers  $RR'CO_2$  the alkyl which is converted into chloride is the smaller of the two:  $Et(C_2H_5)_2CO_2 + PCl_5 = EtCl + ClCO_2C_2H_5 + POCl_3$ . The amides of the chloroformates, which may be regarded as half chloride half amide of carbonic acid (carbamic chlorides), are obtained by the action of  $COCl_2$  upon the hydrochlorides of amines, e.g.  $COCl_2 + NEtH_2 = COCl(NEtH) + HCl$  (Gattermann a. Schmidt, *B.* 20, 118) cf. CHLOROFORMIC ACID.—3. When an alkyl carbonate is heated with an alcohol containing a heavier alkyl, the heavy alkyl displaces the light one (R.).

**Chloro-imido-carbonic ethers**  $ClN:C(OR)_2$ . These are formed by leading chlorine into a cooled solution of  $NaOH$  and  $KCN$  in an alcohol (Sandmeyer, *B.* 19, 862). They are crystalline, and converted by dilute acids or by aqueous  $H_2S$  into the corresponding carbonic ethers. Aqueous potassium arsenite reduces them to imido-carbonic ethers (cf. CHLORO-IMIDO-CARBONIC ETHERS).

**Imido-carbonic ethers**  $HN:C(OR)_2$ . Prepared as above, are alkaline liquids, readily decomposed by aqueous acids into  $NH_3$  and carbonic ethers (cf. IMIDO-CARBONIC ETHERS).

**CARBO-DI-NICOTINIC ACID** v. PYRIDINE TRI-CARBOXYLIC ACID.

**CARBONIC OXIDE.** Name usually given to  $CO$ , v. CARBON, OXIDES OF.

**CARBONIC OXIDE - POTASSIUM** v. potassium salt of HEXAOXY-BENZENE.

**CARBONOUS OXIDE**  $CO$ , v. CARBON, OXIDES OF.

**CARBON TETRA-IODIDE** v. TETRA-IODO-METHANE.

**CARBONIMELIC ACID** v. iso-PENTANE TRI-CARBOXYLIC ACID.

**CARBONYL.** The divalent radicle  $C=O$ . When attached to two carbon atoms the product is a ketone, when attached to one carbon atom and to hydroxyl the compound is a carboxylic acid; when attached to one carbon atom and to one hydrogen atom the product is an aldehyde. Two or three carbonyls attached to  $CH$  render the hydrogen displaceable by metals. Many carbonyl derivatives of amido-compounds are described under the amido-compounds from which they are formed by the action of  $COCl_2$ .

**CARBONYL - DI - m - AMIDO - DI - BENZOIC ACID** v. DI-PHENYL-UREA-DI-m-CARBOXYLIC ACID.

**CARBONYL - AMIDO - PHENOL** v. *Anhydride of Oxy-phenyl-carbamic acid*.

**CARBONYL BROMIDE** v. CARBON, OXY-BROMIDE OF.

**CARBONYL DI-BIURET** v. BIURET.

**CARBONYL-CARBAMIC ETHER**  $C_2H_5NO_3$ , i.e.  $CO:N.CO.OEt$  or  $(C_2H_5NO_3)_2$ . *Carboacetyl cyanate* or *cyanurate*. [119°]. Formed by the action of chloroformic ether on potassium cyanate. If dry ether be present a second compound  $C_{10}H_{15}N_3O_5$  [107°] is also formed. Rhombic plates, sl. sol. of alcohol, v. sol.  $CHCl_3$ . When heated with water to 100° it loses  $CO_2$  forming cyanuric ether. Its formula should therefore possibly be trebled. The compound  $C_{10}H_{15}N_3O_5$  when distilled with water behaves similarly (Wurtz a. Henniger, *C. R.* 100, 1419; *A. Ch.* [6] 7, 132).

### Compounds with cyanic ether

(a)  $C_2H_5N_3O_3$  or  $(CO:NCO.Et)(CO.NEt)$ , [107°]. Formed as above, or together with carboxy-carbamic (imido-diformic) ether [50°], (226°) when the ether is wet. Needles, which lose  $CO_2$  on heating, yielding cyanuric ether (W. a. H.).

(b)  $C_2H_5N_3O_3$ , i.e.  $(CO.N.CO.Et)(CONEt)$ , [123°]. Formed together with imido-diformic ether when  $KCNO$  acts on an aqueous ethereal solution of chloroformic ether for a long time. On distilling it forms cyanuric ether (W. a. H.).

**CARBONYL CHLORIDE** v. CARBON, OXYCHLORIDE OF.

**CARBONYL-GUANIDINE** v. AMIDO-DICYANIC ACID.

**CARBONYL DI-PHENYLENE** v. DIPHENYLENE KETONE.

**CARBONYL-DI-PHENYL OXIDE** v. DIPHENYLENE KETONE OXIDE.

**CARBONYL-PYRROLE**  $C_4H_5N_2O$  i.e.

$OC \begin{smallmatrix} \diagup NC.H \\ \diagdown NC.H \end{smallmatrix} Di-tetrol-urea$ . [63°]. (c. 238°).

Formed, together with di-pyrrol-ketone, by the action of carbonyl chloride upon pyrrol-potassium (Ciamician a. Magnaghi, *B.* 18, 414; 1829). Large monoclinic crystals,  $a:b:c = 1:1.6881:7.189$ . V. sol. alcohol and ether, insol. water. By heating to 250° it is transformed into a mixture of pyrrol-pyrrol  $C_4H_5N.CO.C_4H_5NH$  and di-pyrrol-ketone  $CO(C_4H_5NH)_2$ .

**CARBONYL SULPHIDE** v. CARBON, OXY-SULPHIDE OF.

**CARBONYL-UREA** v. UREA.

**CARBOPETROCENE** v. PETROCENE.

**CARBO - DIPHENYLENE** v. DIPHENYLENE KETONE.

**CARBO-DIPHENYLIMIDE** v. DI-PHENYL-CYANAMIDE.

**CARBO-TRI-PHENYL-TRIAMINE** v. DI-PHENYL-AMIDO-BENZAMINE.

**CARBO-PHENYL-TOLYL-IMIDE** v. PHENYL-TOLYL-CYANAMIDE.

**CARBO-DI-PROPYL-DI-PHENYL-IMIDE** v. DI-PROPYL-DI-PHENYL-CYANAMIDE.

**CARBO - PYRIDENIC ACIDS** v. PYRIDINE CARBOXYLIC ACIDS.

**CARBO-PYROTTRITIC ACID** v. DI-METHYL-FURFURANE CARBOXYLIC ACID.

**CARBO-PYRROLIC ACID** v. PYRROL-CARBOXYLIC ACID.

**CARBO-PYRROLYL-FORMIC ACID** v. PYRRYL-GLYOXYLIC ACID.

**CARBOSTYRIL**  $C_8H_7NO$  i.e.  $C_6H_5 \begin{smallmatrix} \diagup CH:CH \\ \diagdown NH.CO \end{smallmatrix}$  or

$C_6H_5 \begin{smallmatrix} \diagup CH:CH \\ \diagdown N = C(OH) \end{smallmatrix}$ . *Lactam* or *lactim* of *o*-amido-cinnamic acid. (*Py*-3)-*Oxy-quinoline*. [199°].

**Formation.**—1. By boiling *o*-amido-cinnamic acid with  $HClAq$  (Chiozza, *C. R.* 84, 598; *A.* 88, 117; Tiemann a. Oppermann, *B.* 18, 2070).—2. Obtained by reacting tri-chloro-oxy-quinoline with  $HI$  (Rotheit, *J. pr.* [2] 29, 800).

**Preparation.**—*o*-Nitro-cinnamic ether is heated with alcoholic  $(NH_4)_2S$  to 100° under pressure, the solution is evaporated to dryness, taken up with  $NaOH$  and the carbostyril separated.

by  $\text{CO}_2$  (Friedländer & Ostermeyer, *B.* 14, 1916).

**Properties.**—Prisms (from alcohol); or long thin threads (containing aq.) from dilute aqueous solution. May be sublimed.  $\nu$ . sol. cold,  $\nu$ . sol. hot, water. Sol. alcohol and ether. Alkaline  $\text{KMnO}_4$  oxidises it to isatyl and oxaloxyl-amido-benzoic acid (carboxystylo acid).  $\text{CO}_2\text{H.C}_6\text{H}_4\text{.NH}_2\text{C(OH).CO}_2\text{H}$  [200°].

**Salts.**—The K and Na salts form easily soluble plates. The barium salt  $\text{A}_2\text{Ba}$ : sparingly soluble plates.

**Methyl ether:** (247° uncor.). Colourless liquid. Smells of oranges.

**Ethyl ether:** [below 0°]. (256°). Prepared by the action of ethyl iodide on sodium-carboxystyryl, or of alcoholic KOH on chloro-quinoline. Volatile with steam. Colourless liquid. Sweet smell.— $\text{BTCl}$ : hygroscopic crystals.

**Phenyl ether:** (69°). Sublimable. Glistening plates. Sol. ordinary solvents (Friedländer & Ostermeyer, *B.* 14, 335).

**Reference.**—AMIDO-CARBOSTYRYL, BROMO-CARBOSTYRYL, &c. Hydrocarboxystyryl is described under AMIDO-PHENYL-PROPIONIC ACID. Ethylpseudo-carboxystyryl is described as (*lq.* 3, 4)-Oxyethyl-quinoline.

**CARBOSTYRYL-CARBOXYLIC ACID**  $\nu$ . Oxy-quinoline-carboxylic acid.

**CARBOTHIALDINE**  $\text{C}_8\text{H}_{10}\text{N}_2\text{S}_2$ . Crystals which separate on adding  $\text{CS}_2$  to an alcoholic solution of aldehyde-ammonia (Redtenbacher & Liebig, *A.* 65, 43). Also from aldehyde and ammoniac thio-carbamate (Mulder, *A.* 168, 235). Insol. water. Sol. acids.

**Reactions.**—1.  $\text{HCl}$  splits it up into aldehyde,  $\text{NH}_3$  and  $\text{CS}_2$ .—2.  $\text{KMnO}_4$  forms  $\text{H}_2\text{SO}_4$ ,  $\text{CO}_2$ ,  $\text{KCl}$ , and acetic acid.—3.  $\text{HCl}$  and  $\text{FeCl}_3$  forms  $\text{NH}_4\text{Cl}$ , aldehyde, and  $\text{NH}_4\text{C}_2\text{S}_2\text{C}_6\text{H}_4\text{N}_2$  (Guarreschi, *G.* 8, 246; *B.* 11, 1383).

**CARBO-TRI-THIO-HEXABROMIDE**  $\nu$ . HEXABROMO-DI-METHYL TRI-SULPHIDE.

**CARBO-POLYLENE-DI-PHENYL-TRIAMINE**  $\nu$ . DI-PHENYL-TOLYLENE-TETRA-AMIDOMETHANE.

**CARBO-DI-TOLYL-IMIDE**  $\nu$ . DI-TOLYL-CYANAMIDE.

**DICARBOTHIONIC ETHER**  $\text{S}(\text{CO}_2\text{Et})_2$ . (180°). From  $\text{ClCO}_2\text{Et}$  and alcoholic  $\text{Na}_2\text{S}$ . Oil; decomposed by baryta-water or alcoholic KOH into  $\text{Et}_2\text{S}$  and  $\text{CO}_2$  (V. Meyer, *B.* 2, 298).

**CARBO-VALERTHIALDINE**  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{S}_2$ . [109°]. (G.); [117°] (S.). V.D. 60. From isovaleric aldehyde (5g.),  $\text{CS}_2$  (3g.) and aqueous  $\text{NH}_3$  (Schröder, *B.* 4, 469). From isovaleric aldehyde and ammonium thio-carbamate (Mulder, *A.* 168, 237). Colourless needles (from alcohol).  $\text{FeCl}_3$  on warming gives the sulphocyanide reaction.  $\text{KMnO}_4$  forms  $\text{HCN}$ ,  $\text{H}_2\text{SO}_4$ , and valeric acid.  $\text{FeCl}_3$  and  $\text{HCl}$  form in the cold a yellow powder ( $\text{S.CSNH}_2$ ). Carbovalertaldine may therefore be dithiocarbamate of di-valerilidene ammonium  $\text{H}_2\text{N.CS.SN}(\text{CH}_2\text{CH}_2\text{CHMe}_2)_2$  (Guarreschi, *A.* 222, 810; *G.* 13, 500°).

**CARBOVINIC ACID** is Hydrogen Ethyl Carbonate ( $q. v.$ ).

**CARBOXAMIDO-BENZOIC ACID**  $\nu$ . DI-PHENYL-TRIAZO-DI-CARBOXYLIC ACID.

**CARBOXAMIDO-CARBIMIDAMIDO-BENZOIC ACID**  $\nu$ . p. 157.

Vol. I.

**CARBOXAMIDO-CYANAMIDO-BENZOYL**  $\nu$ . p. 155.

**CARBOXAMIDO-HIPPURIC ACID**  $\nu$ . p. 164.

**CARBOXAMIDO-O-OXY-BENZOIC ACID**  $\text{C}_{13}\text{H}_{12}\text{N}_2\text{O}_4$ . A product of the action of urea on amido-salicylic acid at 200° (Griess, *J. pr.* [2] 1, 235). Minute needles,  $\nu$ . sl. sol. most solvents.

**CARBOXETHYL CYANATE or CYANURATE**  $\nu$ . CARBONYL-CARRAMIC ETHER.

**CARBOXY-ACETO-GLUTARIC ACID**  $\nu$ . METHYL PROPYL KETONE TRI-CARBOXYLIC ACID.

$\nu$ -CARBOXY-O-AMIDO-BENZOIC ACID  $\nu$ . ISATOIC ACID.

$\nu$ -Carboxy- $\eta$ -amido-benzoic ether  $\nu$ . p. 157.

**CARBOXY-BENZENE PHOSPHONIC ACID**  $\text{CO}_2\text{H.C}_6\text{H}_4\text{.PO(OH)}_2$  [above 300°]. Prepared by the oxidation of  $p$ -toluene phosphonic acid  $\text{C}_6\text{H}_4(\text{CH}_3)\text{PO(OH)}_2$  with  $\text{KMnO}_4$ . Needles or tables.  $\nu$ . sol. water, m. sol. aqueous  $\text{HCl}$  or alcohol. On heating to 300° it decomposes, giving metaphosphoric and benzoic acids.

**Salts.**— $\text{A}'''\text{Ag}$ : slightly soluble pp.— $\text{A}'''\text{H}_2\text{Kaq}$ : fine needles sol. water, sl. sol. alcohol.— $\text{A}'''\text{H.K}$ : long prisms sl. sol. water.

**Chloride**  $\text{C}_6\text{H}_4(\text{COCl})_2(\text{POCl}_2)_2$ . [83°]. (315°). Colourless crystals. Heated with  $\text{PCl}_5$  it gives  $p$ -chlorobenzoyl chloride  $\text{PCl}_5$  and  $\text{POCl}_3$ .

**Trimethyl ether**  $\text{A}'''\text{Me}$ : thick liquid (Michaëlis & Panck, *B.* 14, 405).

**CARBOXY-BENZOYL-ACETIC ACID**  $\nu$ . ACETOPHENONE DI-CARBOXYLIC ACID, p. 37.

**CARBOXY-BENZOYL-AMIDO-BENZOIC ACID**  $\nu$ . PHTHALOXYL-AMIDO-BENZOIC ACID.

**CARBOXY-BENZOYL-ETHENYL TRI-CARBOXYLIC ACID**  $\nu$ . PHENYL-ETHENYL-KETONE TETRA-CARBOXYLIC ACID.

**CARBOXY-BENZOYL-PROPIONIC ACID**  $\text{C}_{11}\text{H}_{10}\text{O}_5$  i.e.  $\text{CO}_2\text{H.C}_6\text{H}_4\text{.CO.C}_2\text{H}_5\text{CO}_2\text{H}$ . The free acid is unstable, but its Na salt is formed by dissolving phthalyl-propionic acid in  $\text{NaOHaq}$  (Gabriel & Michael, *B.* 11, 1680).

$\nu$ -CARBOXY-BENZOYL-ACETO-ACETIC ETHER

$\text{C}_{11}\text{H}_{10}\text{O}_5$  i.e.  $\text{CO}_2\text{H.C}_6\text{H}_4\text{.CH}_2\text{CHAc.CO}_2\text{Et}$ . [92°]. Formed by reducing phthalyl-aceto-acetic ether with zinc-dust in glacial acetic acid (Bülow, *A.* 236, 190). Needles;  $\nu$ . sol. hot water, alcohol, ether, and  $\text{HOAc}$ . The ammonium salt melts at [121°]. Boiling baryta-water converts it into benzyl-acetone  $\nu$ -carboxylic acid.

**Phenyl hydrazide**  $\text{C}_{20}\text{H}_{12}\text{N}_4\text{O}_4$ . [235°]. Decomposes slowly forming alcohol and  $\text{C}_{10}\text{H}_8\text{N}_2\text{O}_4$  [240°].

**O-CARBOXY-BENZYL-MALONIC ACID**  $\text{HO}_2\text{C.C}_6\text{H}_4\text{.CH}_2\text{CH(CO}_2\text{H)}_2$ . Formed by saponifying  $\nu$ -carboxy-benzyl-malonic ether (Wislicenus, *A.* 242, 37). Prisms.  $\nu$ . sol. hot, sl. sol. cold, water. Heated to 190° gives off  $\text{CO}_2$  and forms  $\nu$ -carboxy-phenyl-propionic acid [166°].

**Salt.**— $\text{A}'''\text{Ag}$ .  $\nu$ . sl. sol. hot water.

**Di-ethyl ether**  $\text{CO}_2\text{H.C}_6\text{H}_4\text{.CH}_2\text{CH(CO}_2\text{Et)}_2$ . [86°]. S. 0.15 at 17°. Formed by reducing phthalyl malonic ether with acetic acid and zinc (Wislicenus, *A.* 242, 32). Fine needles.  $\nu$ . e. sol. ether and hot alcohol, sl. sol. hot water.

**Salts.**— $\text{A}'''\text{Ag}$ : white needles.— $\text{A}'''\text{Na}$ : deliquescent needles.  $\nu$ . sol. alcohol, aq. sol. ether.

**Tri-ethyl-ether**  $\text{A}'''\text{Et}$ . (250°) at 45 mm.

Z Z

**CARBOXY-CARBAMIC ETHER**  $C_6H_{11}NO_4$ , *i.e.*  $NH(CO_2Et)_2$ , [50°]. (226°).

**Formation.**—1. By the action of chloroformic ether on potassium cyanate in the presence of wet ether. A second compound  $C_6H_{11}N_2O_4$  [107°], insoluble in water, is also formed, while a small quantity of yellow oil [170°] is found in the aqueous extract. If absolute alcohol be used instead of ether, the second compound is not formed.—2. Chloroformic ether (34 gr.) and carbamic ether (24 gr.) are heated together at 120°.

**Properties.**—Long prisms. It forms blurbt and alcohol when made with aqueous  $NH_3$ . The salt  $C_6H_{11}NO_4Ag$  crystallises in cubes (Wurtz & Henniger, *A. Ch.* [5] 7, 135).

**CARBOXY-CINNAMIC ACID** *v.* CINNAMIC ACID.

**CARBOXY-CORNICULARIC ACID**  $C_{15}H_{14}O_5$ , *i.e.*  $C_6H_5.C(CO_2H).CH.CO_2H(CO_2H).C_6H_5$ . Formed as a by-product in the reduction of pulvic acid to dihydrocornicularic acid. It was not isolated, but was converted into the lactone by means of acetic anhydride.

Carboxy-cornicularic-lactone

Long felted needles or short prisms. In cold aqueous  $NH_3$  or alkaline carbonates it dissolves forming salts of the formula  $C_{15}H_{11}O_5M$ , but on heating it gives salts of carboxy-cornicularic acid  $C_{15}H_{12}O_5M_2$  (Spiegel, *B.* 15, 1546).

**CARBOXY-CYANAMIDO-BENZOYL** *v.* p. 155.

**DI-CARBOXY-GLUTARIC ACID**  $C_6H_8O_8$ .

*Propylene tetracarboxylic acid.*

**Ethyl ether**  $(CO_2Et)_2.CHLCH:C(CO_2Et)_2$ , (270°-280°). S.G. 1.131 at 15°. From its sodium salt by  $HCl$ . Oil, soluble in alcohol or ether. Boiled with  $HCl$  it gives off  $CO_2$  and forms glutaric acid (*q. v.*) and iso-aconitic ether.  $NaOH$  acts similarly. \*Sodium derivative  $(CO_2Et)_2.CNa.CH:C(CO_2Et)_2$ , [260°]. From malonic ether,  $NaOEt$  and chloroform (Conrad & Gupfzeit, *A.* 222, 251°).  $2(CO_2Et)_2.CNa + CHCl_3 = (CO_2Et)_2.CNa.CH:C(CO_2Et)_2 + 3NaCl$ . Bright yellow prisms. Insol. ether, sl. sol. cold water or cold alcohol, v. sol. hot water or hot alcohol. Gives a violet colour with ferric chloride, and pps. with metallic salts. Sodium amalgam reduces it to dicarboxy-glutaric acid,  $(CO_2H)_2.CH.CH_2.CH(CO_2H)_2$ , [167°]. When this acid is heated it gives off  $CO_2$ , becoming glutaric acid.

**Methyl di-carboxy-glutaric ether.**—Sodium di-carboxy-glutaric ether heated with alcoholic  $Me_2$  at 150° forms methyl-di-carboxy-glutaric ether,  $(CO_2Et)_2.CMe.CH:C(CO_2Et)_2$ , an oil, which on saponification gives rise to  $(CO_2H)_2.CMe.CH:C(CO_2H)_2$ , and this readily splits off  $CO_2$ , forming methyl-glutaric acid,  $CO_2H.CHMe.CH:C(CO_2H)_2$ , [137°]. Methyl glutaric acid forms white crystals; v. sol. water, alcohol, or ether.

**Benzyl-di-carboxy-glutaric ether**  $(CO_2Et)_2.C(C_6H_5).CH:C(CO_2Et)_2$ , [78°], is formed in a similar way, using benzyl chloride. Insol. water, v. sol. hot alcohol, ether, or conc.  $H_2SO_4$ . When saponified by caustic soda it gives off  $CO_2$ , carbonic acid and forms benzyl-glutaric acid  $CO_2H.CH(C_6H_5).CH:C(CO_2H)_2$ , [145°].

**DI-CARBOXY-GLUTARIC ACID** *v.* DI-CARBOXY-GLUTARIC ACID.

**CARBOXYL** *Oxatyl*. The monovalent acid radicle  $CO_2H$  *i.e.*  $CO_2OH$ . Its hydrogen is always displaceable by metals, *cf.* Acids.

**CARBOXYLIC ACID**, so-called, *v.* DI-OXY-BENZENE-DI-QUINONE.

**Di-hydro-carboxylic acid** *v.* TETRA-OXY-QUINONE.

**Tri-hydro-carboxylic acid** *v.* HEXA-OXY-BENZENE.

**Oxy-carboxylic acid** *v.* BENZENE TRI-QUINONE.

**CARBOXY-OXAMIC ACID** *Di-ethyl ether*.  $C_6H_5.FO_2$ , *i.e.*  $CO_2Et.NH.CO.CO_2Et$ , [45°]. From  $ClCO.CO_2Et$  and oxamic ether (Saloman, *J. pr.* [2] 9, 292). Needles (from ether); sol. water and alcohol.

**CARBOXY-PHENOXY-ACETIC ACID**

$C_6H_5(CO_2H).O.CH_2.CO_2H$ . *Carboxy-phenyl-glycollic acid*. [187°]. Formed by oxidation of *o*-aldehydo-phenoxy-acetic acid with  $KMnO_4$ . White needles. Sol. alcohol, ether, and hot water.— $A''Ag_2$ : white, sparingly soluble pp.

*Di-ethyl ether*  $A''Et_2$ : liquid.

*Di-amide*  $C_6H_5O(CO.NH_2)_2$ , [158°]. Long yellow needles, sparingly soluble in ether, benzene, and hot water, v. sol. chloroform and hot alcohol (Rossing, *B.* 17, 2995).

*m*-Carboxy-phenoxy-acetic acid

$C_6H_4(CO_2H).O.CH_2.CO_2H$  [1:3]. [206°]. Prepared by oxidation of *m*-aldehydo-phenoxy-acetic acid with  $KMnO_4$ . Needles; v. sol. alcohol, ether, and acetic acid, sl. sol. cold water.— $A''Ag_2$ : crystalline (Elkan, *B.* 19, 3044).

*p*-Carboxy-phenoxy-acetic acid

$C_6H_4(CO_2H).O.CH_2.CO_2H$  [1:4]. [278°]. Prepared by oxidation of *p*-aldehydo-phenoxy-acetic acid with  $KMnO_4$ . White needles; v. sol. alcohol, ether, and acetic acid, more sparingly in benzene, chloroform, and ligroin, sl. sol. cold water.

**Salts.**— $A''Ag_2$ : white sparingly soluble pp. The  $1^{st}$   $Hu$ , and  $Fe$  salts are sparingly soluble pps.  $Ag_2$   $Cu$  and  $Ba$  salts are soluble (Elkan, *B.* 19, 3044).

**CARBOXY-PHENYL-ACETIC ACID**

$C_6H_5(CO_2H)CH_2.CO_2H$  [1:2]. *Homophthalic acid*, *Phenyl-acetic-carboxylic acid*, *Isuvitic acid*. [174°]. Formed by saponification of benzylcyanide-*o*-carboxylic acid by boiling with dilute  $KOH$ . Colourless crystals. V. sol. alcohol and hot water, insol. benzene.

**Salts.**— $A''Ag_2$ : insoluble amorphous pp.— $A''Ca_2aq$ : sparingly soluble crystalline powder.— $A''Ba$ : easily soluble crystals (Wislicenus, *B.* 18, 173).

prisms; v. sol. ether and chloroform. Formed by the action of acetyl chloride on the acid.

*Ethyl ether*  $A''Et_2$ : (292°); thick aromatic oil (Gabriel, *B.* 20<sup>f</sup> 2499).

[c. 233°]. Formed by dry distillation of the ammonium-salt. Short colourless needles (from alcohol or acetic acid). Sublimes in long crystals. Sl. sol. alcohol. Dissolves in aqueous caustic alkalis. Heated with  $POCl_3$  at 150°.

170° it is converted into di-*o*-chloro-iso-quinoline.

(314°–318°); long colourless needles; v. sol. ordinary solvents. Dissolves in aqueous alkalis. Obtained by dry distillation of the methylamine salt of the acid. By MeI and methyl-alcoholic KOH at 100° it is converted into a tri-methyl

also obtained by methylation of the imide (Gabriel, *B.* 19, 1654, 2354, 2363). The imide and methylimide combine with diazo-benzene in alkaline solution.

*Amic acid*  $C_6H_4(CO_2H).CH_2.CONH_2$  (homophthalamic acid): [187°]; colourless needles. Formed by slowly warming benzyl-cyanide-*o*-carboxylic acid  $C_6H_4(CO_2H).CH_2.CN$  with conc.  $H_2SO_4$  to 70°, and pouring into water.

*Amic methyl ether*  $C_6H_4(CO_2Me).CH_2.CONH_2$ : [112°]; crystalline solid (Gabriel, *B.* 20, 1204).

#### Benzene-azo-carboxy-phenyl-acetic-imide

action of diazo-benzene chloride upon an alkaline solution of the imide of carboxy-phenyl-acetic acid. Orange-yellow needles (Gabriel, *B.* 20, 1205).

#### CARBOXY-PHENYL-BENZ-GLYCOCYAMIDINE v. BENZGLYCOCYAMIDINE.

#### CARBOXY-PHENYL-GLYCOLLIC ACID v.

#### CARBOXY-PHENOXY-ACETIC ACID.

#### CARBOXY-PHENYL-MAJONAMIC ACID.

*Ethyl ether*  $CO_2Et.CH_2.CO.NH.C_6H_4.CO_2H$ . [173°]. A product of the action of malonic ether on *m*-amido-benzoic acid (Schiff, *A.* 232, 144; *B.* 17, 403). Silvery needles. When heated it breaks up into malonic acid and malonyl-di-amido-di-benzoic acid:

*o*-CARBOXY-PHENYL-METHYL-ACETIC ACID  $C_6H_4(CO_2H).CHMe.CO_2H$ . *α*-Methyl-homo-*o*-phthalic acid. *Hydratropic-o*-carboxylic acid. [147°]. Formed by heating the imide with fuming HCl at 200°. Colourless crystalline powder.—*A*"Ag<sub>2</sub>: crystalline pp.

*Di-oxy-methyl-isoquinoline*. [145°]. Formed by heating *o*-cyano-phenyl-methyl-aceto-nitrile  $C_6H_4(CN).CHMe.CN$  with conc.  $H_2SO_4$  at c. 130° and pouring into water. Glistening prisms. Can be distilled undecomposed. Dissolves in aqueous alkalis. By digestion with alcoholic KOH and MeI it is converted into the methyl-imide of carboxy-phenyl-di-methyl-acetic acid

into (*Py.* 2:4:1)-di-chloro-methyl-isoquinoline, whilst (*Py.* 4:2:1)-*o*-chloro-oxy-methyl-isoquinoline is formed as a by-product (Gabriel, *B.* 20, 2503).

#### *o*-Carboxy-phenyl-di-methyl-acetic acid

*phthalic acid*. [c. 123°]. Obtained by dissolving the anhydride in boiling aqueous NaOH and ppg. with HCl. On heating it is reconverted into the anhydride. By distillation with soda lime it gives isopropyl-benzene.—*A*"Ag<sub>2</sub>: crystalline pp.—*A*"K<sub>2</sub>aq: plates.

(312°) at 760 mm. Prepared by heating the imide or methylimide with fuming HCl (4 pts.) at 210° for 4 or 5 hrs. Flat crystals, slowly dissolved by aqueous alkalis, forming salts of the acid.

phthalimide): [120°]; (318°) at 770 mm. Prepared by the action of methyl iodide on a solution of the imide of carboxy-phenyl-acetic acid in methyl-alcoholic KOH at 100°. Flat needles.

methyl-homo-phthalimide). [103°]. (295°) at 770 mm. Formed by further methylation of the preceding imide or of the methylimide of *o*-

Long needles. Slowly sublimates at 100°. V. sol. ordinary solvents, insol. alkalis (Gabriel, *B.* 19, 2363; 20, 1198).

#### CARBOXY-PHENYL-METHYL-*o*-PYRROL-BENZOIC ACID $C_6H_4H_3NO_3$ , i.e. $HO_2C.C_6H_4.NH_2$

$HC.C_6H_4.NH_2$  [210°]. Obtained by saponification of its mono-ethyl-ether which is obtained by several days' standing of an acetic acid solution of acetyl-*o*-aceto-acetic ether (1 mol.) and *m*-amido-benzoic acid (1 mol.). Aggregates of colourless needles. Sol. ordinary solvents except water.

[160°]; slender yellow needles (from dilute acetic acid); sol. alcohol, ether, &c. Its Ca, Ba, Sr, and Mg salts are white granular pps. (Paal a. Schneider, *B.* 19, 3152).

#### *o*-CARBOXY-PHENYL-OXAMIC ACID

*Formation*.—1. By heating acetyl-*o*-aceto-acetic acid with *o*-amido-benzoic acid at 120°. 2. From carbostyryl and alkaline  $KMnO_4$  (Friedlander a. Ostermaier, *B.* 14, 1915; 15, 334).—3. From acetyl-quinoline tetrahydride and cold dilute  $KMnO_4$  (Hofmann a. König, *B.* 16, 734).—4. From cynurin or cyanuric acid and alkaline  $KMnO_4$  (Kretschy, *M.* 4, 156; 5, 16).—5. Formed by oxidation of (*Py.*)-bromo-quinoline with  $KMnO_4$  (Claus a. Collischonn, *B.* 19, 2767).

*Properties*.—Silvery needles (containing aq.) (from water), or needles (from ether). Decomposed by dilute acids, or by long boiling, into oxalic and amido-benzoic acids.

*Salts*.—( $NH_4$ )<sub>2</sub>A": minute felted needles.—KHA"aq.—BaA"aq.—BaA<sub>2</sub>A", aq.—CaA"2aq.—CuA"CuO 4aq.—Ag<sub>2</sub>A".

**Mono-ethyl ether**

$C_2H_5(CO_2H).NH.CO.CO_2Et$ . *Ethyl-oxalyl-anthranilic acid*. [181°]. Felted needles. Formed by oxidation of indoxyl ether or indoxanthin ether with  $CrO_3$  (Baeyer, B. 15, 777).

**m-Carboxy-phenyl-oxamic acid**

$CO_2H.CO.NH.C_6H_4.CO_2H$ . *Oxaloxyl-amido-benzoic acid*.

**Formation.**—1. By boiling an aqueous solution of the barium salt of cyano-carbimido-amido-benzoic acid.—2. By heating (equal mols. of) *m*-amido-benzoic acid and anhydrous oxalic acid for aq. hour at 180° (Griess, B. 16, 336; 18, 2412).

**Properties.**—Small white plates, v. sol. hot water, m. sol. alcohol, insol. ether.—BaA' 2aq.

**Mono-ethyl ether**

$CO_2Et.CO.NH.C_6H_4.CO_2H$  (ethoxal-benzamic acid) [225°]. Formed by boiling *m*-amido-benzoic acid with oxalic ether (Schiff, A. 232, 132; B. 17, 402; G. 15, 534). Silky needle; (from water or alcohol). When heated above 225° it splits up into oxalic ether and carboxy-phenyl-oxamide. **Amide-ether**  $CO_2Et.CO.NH.C_6H_4.CONH_2$  [191.5°]. Got by heating *m*-amido-benzamide with oxalic ether. Gives with aniline the amide-anilide  $CO(NHPh).CO.NH.C_6H_4.CO.NH_2$  [c. 310°]. **Anilide-ether**  $CO_2Et.CO.NH.C_6H_4.CONHPh$  [180°]. From *m*-amido-benzanilide and oxalic ether. Satiny needles.

**Amic acid**  $CO(NH_2).CO.NH.C_6H_4.CO_2H$  v. PHENYL-OXAMIDE CARBOXYLIC ACID.

**CARBOXY-PHENYL-OXAMIDE** v. PHENYL-OXAMIDE CARBOXYLIC ACID.

**CARBOXY-PHENYL-OXY-ACETIC ACID** v. CARBOXY-PHENOXY-ACETIC ACID.

**o-CARBOXY-PHENYL PHENYL-CARBAMATE**  $C_6H_4(CO_2H).O.CO.NHC_6H_5$ .

**Methyl ether**  $C_6H_4(CO_2Me).O.CO.NHC_6H_5$  [238°]; long needles; sublimable. Formed by heating methyl salicylate with phenyleyanate (Snape, B. 18, 2431).

**m-CARBOXY-PHENYL-PHOSPHORIC ACID**  $C_6H_4(CO_2H).O.PO(OH)_2$  [201°]. From its chloride and water. Scales, v. sol. water, alcohol, and ether. Water at 160° decomposes it into phosphoric and *m*-oxy-benzoic acid (Anschütz a. Moore, A. 239, 333).

**Chloride**  $C_6H_4Cl_2PO_3$ , i.e.

$C_6H_4(COCl).O.PO.Cl_2$ . (170°) at 12mm. S.G. 20 1.548. From *m*-oxy-benzoic acid (1 mol.) and  $PCl_5$  (1½ mols.). Further treatment with  $PCl_5$  (1 mol.) produces  $C_6H_4Cl_2PO_3$ . (178°) at 11 mm. This is probably  $C_6H_4(COCl).O.PO.Cl_2$  and is converted by water into  $C_6H_4(CO_2H).O.PO(OH)_2$ . A further quantity of  $PCl_5$  converts  $C_6H_4Cl_2PO_3$  into  $C_6H_4Cl_2CCl_3$ .

**o-CARBOXY-β-PHENYL-PROPIONIC ACID**  $HO_2C.C_6H_4.CH_2.CH_2.CO_2H$  [166°]. Formed by heating *o*-carboxy-benzyl-malonic acid to 190° (Wislicenus, A. 242, 39, cf. Gabriel a. Michael, B. 10, 2204). Prisms, v. sol. hot, sl. sol. cold, water.

**CARBOXY-PHENYL-SEBACAMIC ACID**  $CO_2H.C_6H_4.CO.NH.C_8H_{17}.CO_2H$  [193°]. From its ether by saponification. Prisms.

**Mono-ethyl ether**

$CO_2Et.C_6H_4.CO.NH.C_8H_{17}.CO_2H$  [146°]. From sebacic ether and *m*-amido-benzoic acid (Pellizzari, A. 232, 146; B. 18, 215; G. 15, 550).

**m-CARBOXY-PHENYL-SUCCINAMIC ACID**

$C_6H_4(CO_2H).CO.NH.C_2H_4.CO_2H$ . *Benzamsuccinic acid*. [223°]. Colourless prisms. Its ethyl-ether is formed, together with di-phenyl-succinamide di-carboxylic acid, by boiling amido-benzoic acid with an alcoholic solution of succinic ether. On heating to its melting-point it loses  $H_2O$  and is converted into succinyl-amido-benzoic acid  $C_6H_4 \begin{smallmatrix} \diagup CO \\ \diagdown \end{smallmatrix} N.C_2H_4.CO_2H$  [235°].

**Ethyl ether**

$C_6H_4(CO_2Et).CO.NH.C_2H_4.CO_2H$  [174°]; glistening plates from water.

**Amide**  $C_6H_4(CONH_2).CO.NH.C_2H_4.CO_2H$  [229°].

**Anilide**  $C_6H_4(CONHPh).CO.NH.C_2H_4.CO_2H$  [252°] (Pellizzari, A. 232, 146; B. 18, 214; G. 15, 550; Muretoff, J. R. 4, 298).

**p-Carboxy-phenyl-succinamic acid**

$[4:1] C_6H_4(CO_2H).NH.CO.CH_2.CH_2.CO_2H$  [226°]. From *p*-tolyl-succinimide and dilute aqueous  $KMnO_4$  (Michael, B. 16, 777). Needles, sl. sol. cold water and cold alcohol. Boiling conc.  $HClAq$  gives succinic and *p*-amido-benzoic acids.— $AgHA$ .

**o-CARBOXY-PHENYL-SULPHURIC ACID**

$CO_2H.C_6H_4.O.SO_3.OH$ . *Salicyl-sulphuric acid*. Prepared by the action of  $K_2S_2O_8$  on a solution of salicylic acid in strong  $KOH$ . By heating the K salt to 190° it gives  $K_2SO_4$  and salicylide.— $A''K_2$ . Colourless spikes. Readily decomposed by dilute acids into salicylic acid and  $KHSO_4$  (Baumann, B. 11, 1914).

**m-Carboxy-phenyl-sulphuric acid**

$[3:1] CO_2H.C_6H_4.O.SO_3.OH$ . Prepared by the action of  $K_2S_2O_8$  on a solution of *m*-oxybenzoic acid in strong  $KOH$ .— $A''K_2$ : [220°-225° with decomposition]; needles, more stable towards dilute acids than the *ortho*- compound; is decomposed however at 100°.

**p-Carboxy-phenyl-sulphuric acid**

$[4:1] CO_2H.C_6H_4.O.SO_3.OH$ . Prepared by the action of  $K_2S_2O_8$  on a solution of *p*-oxybenzoic acid in strong  $KOH$ .— $A''K_2$ : leaflets or tables. Does not decompose till heated to 250°.

**CARBOXY-PROPYL-ACETIC ACID** v. ETHYL-SUCCINIC ACID.

**CARBOXY-PYRRYL-GLYOXYLIC ACID**

$C_6NH_4(CO_2H).CO.CO_2H$ . Formed by the oxidation of pyrrole - di - methyl - di - ketone  $(CH_3.CO)_2C_6H_4NH$ , or of pyrrol-methyl-ketone carboxylic acid, with alkaline  $KMnO_4$ . Crystalline; sol. ether, alcohol, and boiling water, insol. benzene.— $A''Ag$ : yellow pp.

**Di-methyl ether**  $A''Me_2$ : [145°]; long colourless needles; m. sol. hot alcohol, sl. sol. ether and benzene. Potash-fusion gives pyrrol di-carboxylic acid (Ciamician a. Silber, B. 19, 1412, 1957; G. 16, 373, 379).

**CARBOXY-TARTRONIC ACID** v. Di-oxy-TARTARIC ACID.

**CARBYLO-DIACETONAMINE** v. p. 27.**CAREYLAMINES** v. CARBAMINES.

**CARDAMOMS, OIL OF**. Employed in medicine as a carminative.

2. *From Ceylon*. The seeds of *Elettaria major* contain 8.6 p.c. of an essential oil which consists of a terpene (170°-178°), terpinene, a solid substance [61°], and terpineol  $C_{10}H_{18}$  (205°-220°). The latter is converted by  $HCl$  into di-pentene hydrochloride,  $C_{10}H_{18}.2HCl$  [52°

and by HI into  $C_{10}H_{16} \cdot 2HI$  [76°]. The terpene also gives a hydrochloride  $C_{10}H_{16} \cdot 2HCl$  [52°]. A solid tetrabromide could not be got (Weber, A. 233, 98).

2. From Malabar. The oil from *Elettaria Cardamomum* slowly deposits crystals of  $C_{10}H_{16} \cdot 3H_2O$  (Dumas a. Péligot, A. Ch. [2] 57, 334).

**CARDOL**  $C_{21}H_{36}O_2$  (?) An oil, occurring with anacardic acid (q.v.), in the pericarp of the cashew nut (*Anacardium occidentale*). It is sol. alcohol and ether. It is not volatile; it blisters the skin. It gives, with basic lead acetate a pp. of  $C_{21}H_{36}(PbAc)_2 \cdot PbO$  (Städeler, A. 63, 137). Anacardic acid  $C_{10}H_{16}(OH)CO_2H$  in alcoholic solution gives with metallic solutions pps. of the salts:  $AgA'$ . —  $CaA' \cdot 2aq$ . —  $BaA' \cdot aq$ . —  $MgA' \cdot aq$ . — Its methyl ether is an oil (Ruhemann a. Skinner, C. J. 51, 663; B. 20, 1861).

**CARICIN**. An oily substance present in the seeds of the Papaw tree (*Carica papaya*) (Peckolt, Ph. [3] 10, 343).

**CARMINAPHE**  $\bar{C}_{17}H_{15}N_3O_2$ .

**CARMINE ACID**  $C_{17}H_{15}O_{10}$ . The colouring matter of cochineal which is obtained from insects of the genus *Coccus*, chiefly *Coccus cacti*. Cochineal contains only 10 p.c. colouring matter (Pelletier a. Caventou, A. Ch. [2] 7, 90; 8, 255; Warren de la Rue, A. 61, 1, 23; Schützenberger, A. Ch. [3] 54, 52; Schaller, B. [2] 2, 414; Méne, C. R. 68, 666; Dieterich, C. C. 1867, 287; Liebermann, B. 18, 1969). The lead salt is ppd. on adding lead acetate to an aqueous infusion of cochineal; by this means the quantity of colouring matter in cochineal may be estimated. Carmine, a red pigment prepared from cochineal, appears to be a compound of carminic acid with alumina, lime, and some organic acid. Cochineal also contains a fat (in which are ethers of myristic acid, of  $C_{17}H_{33}O_2$  and of  $C_{12}H_{25}O_2$  and a waxy substance, coccerin (Raimann, M. 6, 891; Liebermann, B. 19, 328).

**Properties**. — Purple mass, sol. water and alcohol, sl. sol. ether. Its solution forms red pps. with the alkaline earths and with acetates of Pb, Zn, Cu, and Ag. Alum and  $Na_2CO_3$  give the aluminium lake.

**Reactions**. — 1. Boiling dilute  $H_2SO_4$  forms 'carmine-red' and a sugar  $C_6H_{12}O_6$  (Hlaswetz a. Grabowski, A. 141, 329). According to Liebermann the formation of sugar is questionable. — 2. Potash-fusion gives coccinin, oxalic acid, and succinic acid (H. a. G.). — 3. Conc.  $H_2SO_4$  at 130° forms a compound  $C_{12}H_{20}O_{13}$  and rufocecin  $C_{15}H_{16}O_8$  (Liebermann a. Dorp, A. 63, 105). — 4.  $HNO_3$  forms *nitro-coccic acid*  $C_6H_7(NO_3)_2$ . — 5. By distillation with zinc-dust a small quantity of a solid hydrocarbon  $C_{10}H_{16}$  is produced, this forms plates melting at [187°] (Furth, B. 16, 2169).

**Salts**. —  $NaA'$ . —  $KA'$  aq. —  $BaA'$  aq.

**Coccinin**  $C_6H_{12}O_6$ . Prepared as above. Yellow laminae (from alcohol); insol. water, v. sol. alcohol, sl. sol. ether. Sol. alkalis. The alkaline solutions are yellow and absorb oxygen, becoming green and, finally, purple. The solution in conc.  $H_2SO_4$  turns indigo-blue on warming. On distillation with zinc-dust it yields a

small quantity of a hydrocarbon  $C_{10}H_{16}$ , which forms plates melting at [187°]. —  $C_{10}H_{16}(NH_4)O_2$ .

**Acetyl derivative**. Yellow crystals, sol. alcohol and acetic acid, insol. water (Furth, B. 16, 2169).

**Rufocecin**  $C_{15}H_{16}O_8$ . Formed as above. Brick-red powder, sl. sol. warm water and ether, m. sol. alcohol. The ethereal solutions fluoresce green. The alkaline solutions are brown. Conc.  $H_2SO_4$  forms a violet solution. —  $CaC_{15}H_{16}O_8$ .

**Compound**  $C_{25}H_{36}O_{12}$ . Black insoluble powder. Forms violet solutions in  $KOH$  aq. and conc.  $H_2SO_4$ . Both this compound and rufocecin give  $C_{10}H_{12}$  [187°] when distilled over zinc-dust.

**Carmine red**  $C_{17}H_{15}O_2$ . Formed by boiling carminic acid with dilute  $H_2SO_4$  (v. supra). Dark purple mass with green lustre; scarlet when powdered. Alcohol and water form red solutions. Insol. ether. Potash-fusion forms coccinin. Water at 200° forms rufocecin  $C_{15}H_{16}O_8$ . — Salts:  $K_2C_{17}H_{15}O_4$ . —  $CaC_{17}H_{15}O_4 \cdot 2aq$ . —  $BaC_{17}H_{15}O_4 \cdot 2aq$ . —  $ZnC_{17}H_{15}O_4 \cdot 2aq$ . —  $Zn(C_{17}H_{15}O_4)_2 \cdot 2aq$ .

If carmine-red be dissolved in acetic acid, and treated with bromine two products are obtained, named provisionally (a)- and (b)-bromo-carmine. The (a)-bromo-carmine is sparingly soluble in acetic acid and separates in crystals (yield: 10 p.c.), whilst the amorphous (b)-bromo-carmine remains in solution and is ppd. on adding water (the yield is 20 p.c.).

'(a)-Bromo-carmine'  $C_{17}H_{13}BrO_2$  crystallises in colourless needles, [278°], v. sol. alkalis. By boiling with strong aqueous KOH it gives

'(a) - Bromo - thoxy - carmine,' so called,  $C_{16}H_{11}BrO_3$ , which forms colourless crystals, [208°]. By its behaviour on etherification it is shown to contain one  $CO_2H$  and one phenolic OH group. On oxidation with  $KMnO_4$  it yields two bodies: — (a) An acid  $C_{16}H_{11}BrO_4$ , which forms colourless crystals [214°]. By its reactions on methylation it is proved to contain one OH and  $CO_2H$  group, whence it probably has the constitution  $C_6(CH_2)_3Br(OH)(CHO)CO_2H$  or  $C_6H(C_6H_4)_2Br(OH)CO.CO_2H$ . (b) A neutral body  $C_{16}H_{13}BrO_3$ , [195°], which by its reactions is shown to be a di-bromo-oxy-methyl-phthalic anhydride  $C_6MeBr_2(OH)(CO_2O)$  [124:3:5:6].

'(b)-Bromo-carmine,' so called, is the second product of the bromination of carmine-red, and separates in yellow amorphous flocks on adding water to the acetic acid solution. It is v. sol. alcohol, acetic acid, but could not be obtained in a pure state. By boiling with strong aqueous KOH it is converted into

'(B)-Bromo-oxy-carmine'  $C_{17}H_{13}BrO_3$ , which forms glistening yellow needles, [232°]. It is a di-basic acid and forms red salts. On oxidation with  $KMnO_4$  it yields two bodies: — (a) An acid  $C_{16}H_{11}BrO_4$ , which forms colourless prisms (containing aq. and melts at [230°] with evolution of  $CO_2$ ). From its reactions it probably has the constitution  $C_6MeBr_2(OH)(CO_2H)CO.CO_2H$ . (b) A neutral body  $C_{16}H_{13}BrO_3$ , identical with that obtained from the '(a)-bromo-oxy-carmine' (Will a. Leymann, B. 18, 3180).

**CARMUFELLIC ACID**  $C_{12}H_{20}O_{10}$ . An acid said to be formed by the action of  $HNO_3$  on the aqueous extract of cloves. Micaceous scales,

insol. alcohol, ether, and cold water (Muspratt a. Danson, *P. M.* [4] 2, 293).

**CARNAUBA WAX.** Obtained from the leaves of *Copernicia cerifera* in Brazil, and largely used there for making candles. It contains myricylalcohol,  $C_{23}H_{38}CH_2OH$  [85.5°], a hydrocarbon, [59°] and compound ethers derived from the following alcohols and acids: myricylalcohol; an alcohol  $C_{23}H_{38}CH_2OH$  [76°]; a di-hydric alcohol  $C_{23}H_{40}(CH_2OH)_2$  [104°]; and isomeric acids of lignoceric acid,  $C_{23}H_{44}CO_2H$  [72.5°], an acid isomeric or identical with cerotic acid  $C_{26}H_{52}CO_2H$  [79°]; and an oxy-acid of the formula  $C_{19}H_{31}(CH_2OH)(CO_2H)$  or its lactone [103.5°]. The alcohol  $C_{23}H_{38}(CH_2OH)_2$  gives on oxidation an acid  $C_{23}H_{40}(CO_2H)_2$  [102.5°]; and the oxy-acid  $C_{19}H_{31}(CH_2OH)(CO_2H)$  gives the acid  $C_{19}H_{31}(CO_2H)_2$  [90°] (Stürcke, *A.* 223, 283; cf. Lewy, *A. Ch.* [3] 13, 438; Brandes, *T.* 1811, 415). The greater part of the wax is myricyl cerotate and myricyl alcohol.

**CARNINE**  $C_8H_{11}NO_2$ . A substance occurring in extract of meat, and in the product of boiling yeast with water (Weidel, *A.* 158, 353; Schützengerber, *C. R.* 78, 493). Obtained by boiling with water the pp. thrown down from meat extract by lead acetate; the carnine crystallises from the evaporated filtrate (Kruckenberg a. Wagner, *C. C.* 1884, 107). Crystallises with aq. v. sl. sol. cold water, insol. alcohol and ether. Bromine-water converts it into hypoxanthine  $C_8H_7N_3O_2$ .— $BHCl$ : needles.— $BH, PtCl_6$ .

**CARPENE**  $C_{15}H_{24}$ . (156°). Obtained, together with *p*-cresol, by distilling calcium pterocarpate. Oil, smelling of turpentine; resinifies in the air. Forms an oily compound with bromine (Oudemans, *B.* 6, 1125; *A.* 170, 252).

**CARROTIN**  $C_{40}H_{56}$  (?). *Carotene*. The colouring matter of the carrot (*Daucus Carota*) (Wackenroder, *Geiger's Mag.* 33, 144; Zeise, *J. pr.* 40, 297; Husemann, *A.* 117, 200). Occurs also as a normal constituent in the leaves of plants, and in the tomato (Arnaud, *C. R.* 102, 1119; 104, 1533; *Bl.* [2] 46, 487; 48, 64). Inasmuch as no other coloured hydrocarbon is known, carotin probably contains oxygen.

**Preparation.**—The roots are cut up and pressed, dried at 80° and extracted with  $CS_2$ . The juice is ppd. with lead acetate and the pp. also extracted with  $CS_2$ . Carotin, hydrocarotin, and fat are obtained from the  $CS_2$  solutions. The fat is saponified with alcoholic potash. Water and  $BaCl_2$  are added. The pp. is dried and extracted with acetone. On recrystallising from methyl alcohol hydrocarotin separates out first (Reinitzer, *M.* 7, 597).

**Properties.**—Small red plates, v. sol.  $CS_2$ , benzene; v. sl. sol. absolute alcohol; and less sol. 90 p.c. alcohol. Insol. Aq. Rapidly absorbs oxygen from the air. Dissolves in conc.  $H_2SO_4$ , giving a deep blue colour. Yields a derivative  $C_{40}H_{56}I_2$  with iodine; this has a deep green colour, and metallic lustre. Chlorine forms a chloro-derivative [120°].

**Hydrocarotin**  $C_{40}H_{56}O$  (?). [138°].  $[a]_D^{20} = -37.4^\circ$  in  $CHCl_3$  at  $-3.4^\circ$ . Prepared as above. Greatly resembles cholesterol. Colourless, insol. water, v. sol. alcohol, acetone ether,  $CHCl_3$ , and  $CS_2$ . Crystallises from acetone in long

needles, and from methyl alcohol in plates containing water. Resembles Liebermann's cholesterol and Hesse's cuprol but differs from phytoosterin (Reinitzer, *M.* 7, 597).

**Acetyl derivative** [128°]; coloured green by  $H_2SO_4$ , and rose by addition of chloroform.

**Benzoyl derivative** [145°].

**CARTHAMIN**  $C_{11}H_{16}O$ . The colouring matter of safflower (*Carthamus tinctorius*) (Chevreul; Schlieper, *A.* 58, 362). Washed safflower is treated with aqueous  $Na_2CO_3$ , acetic acid is added and pieces of cotton are put in. The carthamin that has been taken up by the cotton is subsequently dissolved off by aqueous  $Na_2CO_3$ , and ppd. by citric acid. Powder with red lustre (from alcohol); sl. sol. water, insol. ether, v. sol. alcohol. Its alcoholic solution is purple. Decomposed by boiling with water or alkalis. Potash-fusion gives oxalic and *p*-oxybenzoic acids (Malin, *A.* 136, 117).

**CARVACROL**  $C_{10}H_{16}O$  i.e.  $C_9H_9MePr(OH)$  [1:4:2]. *Cymenol*. Mol. wt. 150. [c. 0°]. (237° i. v.). S.G. 15 0.986.  $\mu_D^{20} 1.5252$ . H.F. p. 68, 181 ( $(C_9O_2) = 94,000$ ;  $(H_2O) = 63,000$ ) (Stohmann, *J. pr.* [2] 34, 319). Occurs in the essential oil of *Origanum hirtum* and, together with cymene and a terpene, in oil of *Satureja hortensis* and *S. montana*; in oil of mint and of *Thymus Serpyllum* (Jahns, *Ar. Ph.* [3] 16, 277; *B.* 15, 816; Haller, *Bl.* [2] 37, 411; *C. R.* 94, 132; Beyer, *Ar. Ph.* [3] 21, 283).

**Formation.**—1. By boiling carvol (50 pts.) diluted with oil of caraway (50 pts.) with glacial phosphoric acid (12 pts.) for 3 or 4 hours (Lustig, *B.* 19, 11; cf. Vöckel, *A.* 35, 308; 85, 246; Kekulé a. Fleischer, *B.* 6, 1088; Kreyler, *B.* 18, 1704).—2. From camphor (5 pts.) by boiling with iodine (1 pt.) (Kekulé a. Fleischer, *B.* 6, 934; cf. Claus, *J. pr.* 25, 264; Schweizer, *J. pr.* 26, 118; *A.* 40, 329).—3. From bromo-camphor and  $ZnCl_2$  (Schiff, *B.* 13, 1408).—4. Pure camphor cymene is converted into its monosulphonic acid and the latter carefully fused with 3 pts. of KOH (Jacobsen, *B.* 11, 1060; cf. Pott, *B.* 2, 121; H. Müller, *B.* 2, 130).

**Properties.**—Oil.  $FeCl_3$  colours its alcoholic solution green.

**Reactions.**—1. On fusing with KOH isoxycuminic acid  $C_{10}H_8(CO_2H)(OH)CH_3$  [1:2:4] is first formed and finally oxy-terephthalic acid is produced (*B.* 11, 1060).—2.  $P_2S_5$  gives cymene and thio-carvacrol  $C_{10}H_{14}S$ .—3.  $P_2O_5$  forms cresol and propylene.—4.  $FeCl_3$  gives di-carvacrol.—5.  $PCl_5$  forms chloro-cymene.—6. Diazobenzene forms  $C_{10}H_8MePr(OH).N_2.C_6H_5$  [80°–85°] and  $C_{10}H_8MePr(OH).N_2.C_6H_5$  [126°] (Mazzara, *G.* 15, 214).—7. Chloro-acetic acid in presence of an alkali forms carvacryl-glycollic acid  $C_{10}H_{13}O_3CH_2CO_2H$ .—8.  $H_2SO_4$  forms one or two sulphonic acids of the form  $C_{10}H_8MePr(OH).SO_3H$ . According to Jahns one only is formed, its salts being:  $KA^+aq.$ — $AgA^+2aq.$ — $BaA^+5aq.$  *S.* 125 at 15°.— $MgA^+12aq.$

**Sodium salt.**— $C_{10}H_8ONa$ : white crystalline powder.

**Methyl ether**  $C_{10}H_{16}OMe$ . (217°). S.G. 2.954 (Paterno a. Pisati, *B.* 8, 71; *G.* 5, 13). Forms with  $H_2SO_4$  two acids  $C_{10}H_{14}(SO_3H)(OMe)$  whose  $Ba$  salts are  $BaA^+3aq.$ ; v. sl. sol. water, and  $BaA^+5aq.$ , v. sol. water.

**Ethyl ether**  $C_{10}H_{16}OEt$ : (235°); oil having

# CARVOL.

an odour of carrots (Lustig, *B.* 19, 11; *C. C.* 1884, 787).

**Acetyl derivative.**  $C_{10}H_{13}OAc$ : (246°). S.G. 1.011; colourless liquid heavier than water.

**Benzoyl derivative**  $C_{10}H_{13}OBz$ : (above 260°); thick odourless oil.

**Di-carvacrol.**  $C_{20}H_{26}O_2$ . [154°]. Formed by the action of neutral  $FeCl_3$  on carvacrol (Dianin, *J. R.* 14, 141). Thin silky needles (from dilute alcohol); insol. water, v. sol. alcohol and ether.

**o-CARVACROTIC ACID**  $C_{10}H_{12}(OH)CO_2H$ . *Oxy-cymene-carboxylic acid.* [136°]. Prepared by passing  $CO_2$  over heated sodium carvacrol. White silky needles. Sublimable. V. sol. hot water, alcohol, and ether, nearly insol. cold water. Alcoholic  $FeCl_3$  gives a violet coloration (Lustig, *B.* 19, 18).

**p-Carvacrotic acid**  $C_{10}H_{12}(OH)CO_2H$ . *Oxy-cymene-carboxylic acid.* [80°]. Obtained by oxidation of carvacrotic aldehyde (from carvacrol,  $CHCl_3$ , and  $NaOH$ ) with  $KMnO_4$ . Long white silky needles. Can be sublimed and distilled with steam. V. sol. hot water, alcohol, and ether, nearly insol. cold water. Green coloration with alcoholic  $FeCl_3$  (Lustig, *B.* 19, 16).

**p-CARVACROTIC ALDEHYDE**  $C_9H_9(CH_3)(C_3H_7)(OH)(CHO)$  [1:4:2:5] (?) *Oxy-aldehydo-cymene.* (c. 236°). Formed by heating carvacrol with aqueous  $NaOH$  and chloroform. Oil. Volatile with steam (Lustig, *B.* 19, 14).

An isomeride [96°] has also been described as *p*-carvacrotic aldehyde. It is left as a residue after distilling off the volatile aldehyde with steam. White silky flat plates. Easily soluble in alcohol, ether, and benzene, sparingly in hot water, insoluble in cold water (Nordmann, *B.* 17, 2632).

**CARVACRYL-AMINE**  $C_{10}H_{13}NH_2$ . *Methyl-propyl-phenyl-amine.* (242°). Formed, together with di-carvacryl-amine, by heating carvacryl with ammoniacal  $ZnBr_2$  or  $ZnCl_2$  and  $NH_4Br$  or  $NH_4Cl$  at 350°-360°; yield, 25% to 30 p.c. Colourless oil, which solidifies at -16°  $BzH_2Cl_2PtCl_4$ : yellow prisms, sl. sol. hot water.

**Acetyl derivative**  $C_{10}H_{13}NHAc$ : [115°]; white glistening tables; sl. sol. hot water, v. sol. warm alcohol.

**Benzoyl derivative**  $C_{10}H_{13}NHBz$ : [102°]; flat glistening crystals; nearly insol. water, sl. sol. cold alcohol, v. sol. hot alcohol, and benzene (Lloyd, *B.* 20, 1261).

**Di-carvacryl-amine**  $(C_{10}H_{13})_2NH$ . (344°-348°). Formed as above, the yield is 27 to 40 p.c. Colourless oil. V. sol. alcohol, ether, and benzene. Its solution in conc.  $H_2SO_4$  is coloured blue by nitrites and nitrates.  $BzHCl$ .  $BzH_2Cl_2PtCl_4$ .

**Acetyl derivative**  $(C_{10}H_{13})_2NHAc$ : [78°]; white glistening scales; v. sol. hot alcohol and ligroin, sl. sol. in the cold (Lloyd, *B.* 20, 1261).

**CARVACRYL-GLYCOLIC ACID**  $C_{12}H_{16}O_3$  i.e.  $C_{10}H_{13}O.CH_2.CO_2H$ . [140°]. From carvacrol, chloro-acetic acid and potash (Spica, *G.* 10, 345). Flat needles.  $-PbA'$ .  $-AgA'$ .

**Ethyl ether EtA'**. [c. 100°]. (289°). **Amide**  $C_{12}H_{18}O_3.NH_2$ . [68°].

**CARVACRYL-LACTIC ACID**  $C_{13}H_{18}O_3$  i.e.  $C_{10}H_{13}O.CMeH.CO_2H$ . [74°]. From carvacrol,  $\alpha$ -chloro-propionic acid, and potash (Seichilone,

*G.* 12, 49). Prisms, v. e. sol. alcohol, ether, and chloroform.

**CARVACRYL MERCAPTAN**  $C_{10}H_{13}S$  i.e.  $C_9H_9MePr(SH)$  [1:4:2]. (236°). S.G. 1.73-1.998. From camphor or carvacrol and  $P_2S_5$  (Flesch, *B.* 6, 478; Roderburg, *B.* 6, 669; Kekulé & Fleischer, *B.* 6, 934). Liquid.  $HNO_3$  oxidises it to sulphotoluic acid (Bechler, *J.* 14, [2] 8, 168).

**Salts.**  $-Hg(C_{10}H_{13}S)_2$ . [109°] (Fittien, *A.* 172, 327).  $-C_{10}H_{13}S.HgCl$ .  $-C_{10}H_{13}SAg$ .  $-C_{10}H_{13}SAgAgNO_3$ .

**Methyl ether**  $C_{10}H_{13}SMe$ . (244°). S.G. 99.

**TRI-CARVACRYL PHOSPHATE**  $PO(OC_{10}H_{13})_3$ . [75°]. Colourless prisms or tables. Easily soluble in alcohol, ether, and benzene, more sparingly in petroleum-ether. Formed by heating carvacryl with  $POCl_3$ ; yield, 55-60 p.c. of the theoretical (Köessler, *B.* 18, 1704).

**CARVACRYL-PHOSPHORIC ACID**  $C_9H_9MePr.O.PO_3H_2$  [1:4:2]. Formed by the action of  $POCl_3$  upon carvacryl, and treatment with aqueous  $K_2CO_3$ . The potassium salt  $A'K5aq$  forms large silvery plates. By alkaline  $KMnO_4$  it is oxidised to oxyisopropyl-salicylic acid  $C_9H_9(CMe.OH)(OH)CO_2H$  [4:2:1] (Heymann & Königs, *B.* 19, 3309).

**TETRA-CARVACRYL SILICATE**  $Si(OC_{10}H_{13})_4$ . (380°-390°) at 118 mm. Colourless oil. Formed by heating carvacryl with  $SiCl_4$ ; the yield is 85 p.c. of the theoretical (Hertkorn, *B.* 18, 1694).

**CARVACRYL-SULPHURIC ACID**  $C_9H_9MePr.O.SO_3H$  [1:4:2]. *Cumyl-sulphuric acid.* The potassium salt is formed by adding potassium pyrosulphate to a warm solution of carvacryl in aqueous  $KOH$ . Silvery plates. V. sol. water and alcohol. By alkaline permanganate it is oxidised to oxyisopropyl-salicylic acid  $C_9H_9(CMe.OH)(OH)CO_2H$  [4:2:1] (Heymann & Königs, *B.* 19, 3309).

**CARVENE.** A terpene present in oil of caraway, v. TERPENES.

**Nitroso-carvene** = CARVOXIM.

**CARVOL**  $C_{10}H_{16}OH$ . (219°). Thick fluid. Formed by reduction of carvol with sodium and alcohol. With phenyl cyanate it reacts to form carveyl-phenyl-carbamate [84°] (Leuchart, *B.* 29, 114).

**CARVEYL PHENYL-CARBAMATE**  $C_{10}H_{13}O.CO.NPhH$ . [84°]. Formed by the action of phenyl cyanate upon carvol  $C_{10}H_{13}OH$ . Slender needles. V. sol. hot alcohol, sl. sol. ether and ligroin (Leuchart, *B.* 20, 114).

**CARVOL**  $C_{10}H_{16}O$ . (228°) (R. Schiff, *B.* 19, 562). S.G. 1.4967 (Gladstone, *C. J.* 49, 621);  $n_D^{20}$  1.5574 (Flückiger, *Ar. Ph.* [3] 22, 361).  $\mu$ , 1.5020 (G.).  $R$ , 7668 (G.). S.V. 190-200. H.F.p. 48,250 ( $(C_{10}O) = 91,000$ ;  $(H_{20}O) = 69,000$ ) (Stohmann, *J. p.* [2] 34, 322).

**Occurrence.**—In oil of caraway (*oleum carvi*) together with carveol (173°) (Völkel, *A.* 85, 246). In oil of dill (*Anethum graveolens*) and of mint (*Mentha crispata*). The carvol in the oils of caraway and of dill is dextro-rotatory, but that from oil of mint is laevo-rotatory  $[\alpha]_D^{20} = -62.46$  at 2° (Beyer, *Ar. Ph.* [3] 21, 286). According to Flückiger (*Ar. Ph.* [3] 22, 361) the rotatory power of carvol is  $[\alpha]_D^{20} = 58.2^\circ$ .

**Properties.**—Liquid. Carvol from all three sources forms the same crystalline compound  $(C_{10}H_{16}O)_2.H_2S$  [187°] when  $H_2S$  is passed into its alcoholic solution. When prepared from oil

of caraway or of dill this compound is dextro-rotatory,  $[\alpha]_D = +5.5^\circ$  at  $20^\circ$ , but when obtained from oil of mint it is laevo-rotatory,  $[\alpha]_D = -5.5^\circ$  at  $20^\circ$ . Dilute alcoholic KOH in the cold liberates carvol from this compound. Protracted treatment with  $H_2S$  converts carvol in alcoholic solution into the amorphous  $(C_{10}H_{13}S)_2H_2S$ .

**Reactions.**—1. Distillation over solid KOH or  $P_2O_5$  changes carvol into the isomeric carvacrol (Kekulé a. Fleischer, *B.* 6, 1088).—2.  $Ps$ , forms cymene.—3.  $Ps$ , gives thio-carvacrol  $C_{10}H_{13}SH$ .—4. Distillation over heated zinc dust gives  $C_{10}H_{16}$  (173°) and cymene (Arndt, *Z.* [2] 4, 730; *B.* 1, 204).—5. Sodium in alcohol forms carveol (*g. v.*).—6. Dry HCl gas passed into a mixture of carvol (1 mol.) and aceto-acetic ether (1 mol.) forms the compound  $C_{16}H_{22}ClO_4$ , possibly  $C_8H_{13}Cl \cdot C(OH) \cdot CH(CO_2CH_3)_2$  (146°). (Glistening white prisms (Goldschmidt a. Kisser, *B.* 20, 489).—7. Hydroxylamine forms the oxim, v. Carvoxim.

**Carvol-phenyl-hydrazide**  $C_{10}H_{13}N_2HC_6H_5$ , [106°]. Formed by the action of phenyl-hydrazine on carvol (Goldschmidt, *B.* 17, 1578). Slender white needles. Sol. hot water.

**Carvol-chloro-hydride**  $C_{10}H_{13}ClO$ . *Hydrochlorocarvol*. Oil. Formed by leading dry HCl into carvol.

**Oxim**  $C_{10}H_{13}Cl(NO)$ : [132°]; tables. Formed by the action of hydroxylamine upon carvol-chloro-hydride or of HCl upon carvoxim.

**Benzoyl-oxim**  $C_{10}H_{13}Cl(NO_2)$ : [115°]; needles (from petroleum-spirit) (Goldschmidt a. Zürrer, *B.* 18, 2220).

**Phenyl-hydrazide**  $C_{10}H_{13}Cl(N_2HPh)$ : [137°]; small white prisms.

**Carvol bromo-hydride**  $C_{10}H_{13}BrO$ . Oil. Decomposing at about  $50^\circ$ .

**Oxim**  $C_{10}H_{13}Br(NO)$ : [116°]; prisms (from ligroin).

**Phenyl-hydrazide**  $C_{10}H_{13}Br(N_2HPh)$ : [119°]; slender yellow needles (Goldschmidt a. Kisser, *B.* 20, 488, 2071).

#### Constitution of carvol.

(Goldschmidt, *B.* 20, 490). According to Gladstone (*C. J.* 49, 621) the presence of two pairs of doubly-linked atoms of carbon in the molecule of carvol is indicated by its molecular refraction.

**CARVOXIM**  $C_{10}H_{13}N(OH)$ . *Nitroso-hesperidene* or *nitroso-carvene*. [71°]. Large colourless transparent plates. Sol. oils and alkalis.

**Formation.**—1. By the action of hydroxylamine upon carvol.—2. By passing nitrosyl chloride into a methyl-alcoholic solution of carvene, and heating to its melting-point the crystalline hydrochloride  $C_{10}H_{13}ONCl$  which precipitates.

**Reactions.**—1. By heating with dilute  $H_2SO_4$ , carvol is regenerated.—2. By passing HCl gas into its methyl-alcoholic solution the oxim of carvol chloro-hydride (*v. supra*) is formed.

**Hydrochloride** B'HCl; white crystalline

solid; decomposed by water; formed by passing HCl into the ethereal solution.

**Methyl ether**  $C_{10}H_{13}N(OMe)$ : colourless fluid.

**Benzoyl derivative**  $C_{10}H_{13}N(OBz)$ : [95°], white glistening needles, v. sol. alcohol and benzene (Goldschmidt a. Zürrer, *B.* 17, 1577; 18, 1729).

**Iso-carvoxim**  $C_{10}H_{13}N(OH)$ . [143°], possibly  $\text{CPr} \begin{array}{c} \text{CH.C(=O)} \\ \text{CH}_2 - \text{CH} \end{array} \text{CMe}$ . Obtained, together with a small quantity of carvoxim, by the action of excess of hydroxylamine on a solution of carvol chlorohydride or bromo-hydride in alcohol (Goldschmidt a. Kisser, *B.* 20, 2071). Needles, sl. sol. alcohol; sol. acids and alkalis. Unlike carvoxim, it does not combine with HCl or HBr. Dilute  $H_2SO_4$  forms carvacrol and a compound  $C_{10}H_{13}NO$  [94°].

**Benzoyl derivative**  $C_{10}H_{13}N(OBz)$ : [112°]; scales, v. sol. alcohol.

**CARVYLAMINE**  $C_{10}H_{13}NH_2$ . Formed by reduction of carvoxim  $C_{10}H_{13}NOH$  in alcoholic solution, by sodium-amalgam and acetic acid. Colourless liquid, of strongly aromatic basic odour. Readily absorbs  $CO$ , from the air.—B'HCl: [c.  $180^\circ$ ], slender silky needles (from alcohol).

**Benzoyl derivative**  $C_{10}H_{13}NHBz$ : [169°]; white needles (Goldschmidt a. Kisser, *B.* 20, 486).

**CARYOPHYLLIN**  $C_{10}H_{13}O_4$  (?) A substance that may be extracted by alcohol from cloves, the dried flower-buds of *Caryophyllus aromaticus* (Mylius, *B. J.* 22, 452; Muspratt, *Ph.* 10, 313). Silky needles in stellate groups; sublimes at about  $285^\circ$ . Sl. sol. cold alcohol, sol. boiling alkalis.  $PCl_5$  forms  $C_{10}H_{13}O_4Cl$  and  $C_{10}H_{13}O_4Cl_2$ .

**Acetyl derivative** [184°]. Monoclinic crystals (Hjelt, *B.* 13, 800).

**Caryophyllie acid**  $C_{10}H_{13}O_{12}$ . From caryophyllin and fuming  $HNO_3$  (Mylius, *J.* 6, 1053). Amorphous; sl. sol. water, v. sol. alcohol, ether, and HOAc. May be crystallised from fuming  $HNO_3$ .

**Salts.**— $Na_2A'''$ .— $Ag_2A'''$ .— $Ba_2A'''$  1 $\frac{1}{2}$  aq.

**CASCARILLIN**  $C_{17}H_{19}O_4$ . [205°]. S. 127 at  $100^\circ$ ; S. (alcohol) 3:33 at  $8^\circ$ . Extracted from cascarilla bark (from *Croton Eleutheria* and *Cascarilla*) by boiling water (Mylius, *B.* 6, 1051; cf. Tuson, *C. J.* 17, 195; Duval, *J. Ph.* [3] 8, 91). Minute prisms (from alcohol); tastes bitter. Not affected by boiling dilute HCl. Cascarilla bark also contains a volatile oil (173°–180°).

**CASEIN** v. PROTEINS.

**CASEOSE** v. PROTEIDS.

**CASSONIC ACID**  $C_8H_8O_4$ . Formed, together with accharic and oxalic acids, in the oxidation of cane sugar by  $HNO_3$  (Siewert, *Institut.* 21, 78). Also from glyconic acid and  $HNO_3$  (Hönig, *J.* 1879, 667). Syrup. Reduces ammoniacal  $AgNO_3$  to a mirror.—BaA'' 2 aq.

**CASTORIN**. Castoreum is a hard black substance (soft when fresh) found in a pair of small sacs situated in the genital organs of the beaver (*Castor fiber* and *americanus*). An alcoholic extract deposits first fat, and then castorin. Castoreum also contains a volatile pungent oil,

cholesterin, a resin, proteids,  $\text{CaCO}_3$ , and inorganic salts (Valenciennes, *J.* 1861, 803).

**CASTOR OIL.** A fatty oil obtained by pressure from the seeds of *Ricinus communis*. It solidifies at about  $-18^\circ$ , has S.G. about .969 at  $12^\circ$ , and is dextro-rotatory,  $[\alpha] = 12^\circ$  (Popp, *Ar. Ph.* [2] 145, 233). Castor oil consists chiefly of glycerides of stearic and ricinoleic acids. It is completely dissolved by 5 vols. of 90 p.c. alcohol (Hager, *C. C.* 1876, 389). Dry distillation gives acrolein, cenanthol (heptioic aldehyde) and an acid  $(\text{C}_{11}\text{H}_{20}\text{O}_2)_2$  (Bussy a. Lecanu, *J. Ph.* 13, 57; Stanek, *J. pr.* 63, 138; Leeds, *B.* 16, 290; Knauff a. Brunner, *B.* 17, 2985).  $\text{HNO}_3$  oxidises it to heptioic, oxalic, azelaic, suberic, and ( $\beta$ )-pinic acids (Arppe, *A.* 120, 288). The products obtained by saponifying castor-oil and distilling the resulting alkaline ricinolate alone or with NaOH are methyl hexyl ketone, sec-octyl alcohol, and sebacic acid (Neison, *C. J.* 27, 507, 837). Conc.  $\text{H}_2\text{SO}_4$  converts castor oil into ricinyl-sulphuric acid  $\text{C}_{11}\text{H}_{20}\text{O}_2\text{OSO}_3\text{H}$ , which by the addition of water breaks up into ricinoleic acid and  $\text{H}_2\text{SO}_4$ . From the fatty acids derived from the Turkey-red oil prepared from castor oil, crystals of a di-oxy-stearic acid separate after some time (Benedikt a. Ulzer, *M.* 8, 217).

**CATALPIC ACID**  $\text{C}_{11}\text{H}_{14}\text{O}_6$ . [206°]. Extracted by ether from decoctions of the siliqueous capsule of the *Bignonia Catalpa*. It may be isomeric with hydrocaridic acid (Sardo, *C.* 14, 134). Large white crystals, v. sl. sol. water, sol. alcohol and ether. —  $\text{BaC}_2\text{H}_3\text{O}_6$  6aq: white glistening laminae. —  $\text{Ag}_2\text{A}^+$ : a white pp.

#### CATALYSIS v. CHEMICAL CHANGE.

**CATECHINS**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  3aq (Hlasiwetz; Cross a. Bevan, *C. J.* 41, 92);  $\text{C}_{15}\text{H}_{10}\text{O}_8$  (Etti, *M.* 2, 547);  $\text{C}_{15}\text{H}_{10}\text{O}_8$  (Liebmann a. Taubert, *B.* 13, 694);  $\text{C}_{15}\text{H}_{10}\text{O}_8$  and  $\text{C}_{15}\text{H}_{10}\text{O}_8$  (Gautier, *C. R.* 85, 668). This name has been given to various compounds contained in catechu or Terra japonica which is extracted by boiling water from the fruits or twigs of a variety of plants: Bombay catechu from the fruit of *Acacia Catechu*, Bengal catechu from twigs and unripe pods of *Acacia* (or *Mimosa*) *Catechu*, Gambir catechu from *Nauclaea* (*Uncaria*) *Gambir*, and Nubian catechu from some *Acacia*. Catechu is used in dyeing.

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  (Gautier, *C. R.* 85, 752);  $\text{C}_{15}\text{H}_{10}\text{O}_8$  3aq (C. a. B.);  $\text{C}_{15}\text{H}_{10}\text{O}_8$  5aq (L. a. T.). [217°]. S. (alcohol) 20 at  $15^\circ$ ; S. (ether) 8 at  $15^\circ$  (Wackenroder, *A.* 37, 311). Obtained from Bombay catechu by washing with water and crystallising from acetic ether (L. a. T.; Löwe, *F.r.* 13, 113; Zwenger, *A.* 37, 320; Neubauer, *A.* 96, 337; Kraut a. Van Delden, *A.* 128, 285; Hlasiwetz a. Malin, *A.* 131, 118; Etti, *A.* 186, 337; Schützenberger, *Bl.* [2] 4, 5; Sacc, *C. R.* 53, 1102).

**Properties.**—Small needles (from water). V. sl. sol. cold water, v. sol. hot water and acetic ether. The aqueous solution is coloured green by  $\text{Fe}_2\text{Cl}_6$ . The solution in KOH aq. absorbs oxygen, turning brown. Lead acetate gives in aqueous solution a pp. of  $(\text{C}_{15}\text{H}_{10}\text{O}_8)_2\text{PbO}$  (?) Catechin solutions are ppd. by albumen, but not by gelatin.

**Reactions.**—1. Boiling dilute  $\text{H}_2\text{SO}_4$  forms catechuratin. —2. With HCl and  $\text{KClO}_4$  it gives

$\text{C}_{15}\text{H}_{10}\text{Cl}_2\text{O}_{12}$  (?) (Cross a. Bevan, *C. J.* 41, 92) which is turned crimson by  $\text{Na}_2\text{SO}_3$ . Catechutannic acid does the same. —3. Br gives bromocatechuratin  $\text{C}_{15}\text{H}_8\text{Br}_2\text{O}_8$ , a red insoluble powder. 4. Water and  $\text{P}_2\text{O}_5$  give  $\text{C}_{15}\text{H}_{10}\text{O}_8$ , an elastic insoluble mass. —5. HOAc and  $\text{BaO}_2$  give  $\text{C}_{15}\text{H}_{10}\text{O}_8$ , a colourless powder which melts below  $100^\circ$  (Schützenberger a. Rack, *Bl.* 4, 8). —6. Aqueous  $\text{K}_2\text{Cr}_2\text{O}_7$  forms  $\text{C}_{15}\text{H}_8\text{O}_{10}$ , a brown insoluble powder. —7. Polish-fusion gives phloroglucin and protocatechuic acid (Hlasiwetz, *A.* 131, 118). —8. Dry distillation gives pyrocatechin. —9. Boiling dilute  $\text{H}_2\text{SO}_4$  forms insoluble  $\text{C}_{15}\text{H}_{10}\text{O}_8$  (Neubauer, *A.* 96, 356), or  $\text{C}_{15}\text{H}_{10}\text{O}_{12}$  (Etti). —10. Boiling dilute KOH forms  $\text{C}_{15}\text{H}_{10}\text{O}_8$  (?) a brown powder, sol. alcohol and alkalis. —11. III gives iodoform and other products (G.).

**Di-acetyl derivative**  $\text{C}_{15}\text{H}_{10}\text{O}_8(\text{OAc})_2$ : [131°]; needles or prisms. Soluble in ordinary solvents except water and ligroin (L. a. T.).

**Di-benzoyl derivative**  $\text{C}_{15}\text{H}_{10}\text{O}_8(\text{OBz})_2$ . Flocculent brown substance (S. a. R.).

**Diacetyl-dichloro-catechin**  $\text{C}_{15}\text{H}_8\text{Cl}_2(\text{OAc})_2$ : [169°]; needles. Sol. alcohol, sl. sol. ether.

**Diacetyl-bromo-catechin**

$\text{C}_{15}\text{H}_7\text{Br}(\text{OAc})_2$ : [120°]. White needles. Sol. alcohol, sl. sol. ether.

**Catechuratin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  6aq (?) or  $\text{C}_{15}\text{H}_{10}\text{O}_{12}$ . Formed by passing HCl into a boiling alcoholic solution of catechin (Kraut a. Delden, *A.* 128, 291). Formed also by heating catechin with conc. HCl at  $170^\circ$ . Dark reddish-brown insoluble powder. Not changed at  $190^\circ$ .

**Di-benzoyl derivative**  $\text{C}_{15}\text{H}_8\text{Bz}_2\text{O}_8$  (?) Formed, together with di-benzoyl-catechin by heating catechin with  $\text{BzCl}$  at  $190^\circ$ . Brown mass.

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  2aq. [205°]. S. 9-9 at  $50^\circ$ . Occurs according to Gautier (*C. R.* 86, 668) in Gambir-catechu together with the two following catechins; they are extracted by alcohol and crystallise after evaporation with exclusion of air. Monoclinic prisms.

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  aq. [177°]. Minute needles (v. supra).

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  aq. [163°]. S. 5-3 at  $50^\circ$ . Minute needles (v. supra).

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$  aq. According to Etti (*M.* 2, 547) this is the formula of the catechin in Gambir and Pegu catechins. At  $100^\circ$  it becomes  $\text{C}_{15}\text{H}_{10}\text{O}_8$  at  $160^\circ$  catechutannic acid  $\text{C}_{15}\text{H}_{10}\text{O}_{12}$  and at  $180^\circ$   $\text{C}_{15}\text{H}_{10}\text{O}_8$ . The latter is also got by heating catechin for some time with dilute  $\text{H}_2\text{SO}_4$ .

**Reactions.**—1. **Diazobenzene chloride** gives  $(\text{C}_6\text{H}_5\text{N}_2)_2\text{C}_{15}\text{H}_{10}\text{O}_8$ , a red crystalline pp. sol. alcohol and ether; it dyes wool golden-brown. —2. Dilute  $\text{H}_2\text{SO}_4$  (1:8) at  $140^\circ$  gives phloroglucin and pyrocatechin.

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$ . [165°]. In mahogany (*Acacia*) (Gautier, *Bl.* [2] 30, 568). Latour a. Cazeneuve (*Bl.* [2] 24, 119) give this catechin the formula  $\text{C}_{15}\text{H}_{10}\text{O}_8$ .

**Catechin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$ . [140°]. In brown catechu (G.).

**CATECHOL v. PYROCATECHIN.**

**CATECHUIC ACID v. CATECHIN and PROTOCATECHUIC ACID.**

**CATECHUTANNIC ACID**  $\text{C}_{15}\text{H}_{10}\text{O}_{12}$  (?) or  $\text{C}_{15}\text{H}_{10}\text{O}_{13}$  (?) Extracted by water from catechu.

Formed also by heating catechin alone at 130°, with water at 110°, or by boiling it with alkalis, lime, or  $\text{Pb}(\text{OH})_2$  (Ettli, *A.* 186, 332; Löwe, *J. pr.* 105, 32, 75; Z. [2] 5, 538; *Fr.* 12, 285). Dark reddish-brown powder. V. sol. acetic ether, v. e. sol. alcohol, insol. ether; m. sol. water. It oxidises in the air. It gives a greyish-green pp. with  $\text{Fe}_2\text{Cl}_6$ . It does not pp. tartar-emette. Its aqueous solution is ppd. by gelatin, albumen, and by dilute  $\text{H}_2\text{SO}_4$ . At 162° it changes to  $\text{C}_{12}\text{H}_{10}\text{O}_8$  (?) which resembles catechutannic acid in all respects —  $(\text{C}_{12}\text{H}_{10}\text{O}_8)_3\text{PbO}$ .

**CATHARTIC ACID.** The active principle in senna leaves. It is a glucoside. It contains only C, H, and O. Its Ba and Pb salts are amorphous (Kubly, *Zbl.* [2] 7, 356; Stockman, *Ph.* [3] 15, 749; cf. Lassaigne a. Feneuille, *A. Ch.* [2] 16, 18; Bourgoin, *C. R.* 73, 1449).

**CAULOSTERIN v. CHOLESTERIN.**

**CEDAR OIL.** Obtained by distilling with water the wood of *Juniperus virginiana*. Contains cedrene and cedar-camphor. According to Bertagnini (*C. R.* 35, 800) it contains a compound which combines with  $\text{NaHSO}_4$ .

**Cedar-camphor**  $\text{C}_{15}\text{H}_{20}\text{O}$ . [74°]. (282°). V.D. 8.4 (calc. 7.7). Crystalline mass smelling like cedar-wood. V. sl. sol. water, v. sol. alcohol. Distillation with  $\text{P}_2\text{O}_5$  splits it up into water and cedrene (Walter, *A. Ch.* [3] 1, 498).

**CEDBENE**  $\text{C}_{15}\text{H}_{24}$ . (237°). S.V. 7.6. S.G. 15.984. Obtained as above (Walter, *loc.*).

**Cedrene.** From oil of sage (English).  $\text{C}_{15}\text{H}_{24}$ . (260°). S.G. 15.915. Yellow or green oil. Inactive. Resinified by  $\text{H}_2\text{SO}_4$  (4:1) even at 0°. Gaseous HCl turns an ethereal solution purple. The refractive index seems to indicate four C:C groups (M. M. P. Muir, *C. J.* 27, 686).

The name Cedrene has been used as a generic name for the hydrocarbons  $\text{C}_{15}\text{H}_{24}$ , which occur in the oils of cedar, cloves, patchouli, cubeb, calamus, cascarilla, rosewood, &c. (v. TERPENES). Cedrenes closely resemble the terpenes in their optical properties, which point to the existence of 1½ pairs of doubly linked carbon atoms (Gladstone, *C. J.* 49, 617).

**CEDRINET v. CERULIGNON.**

**CELLULOSE.**  $[\text{C}_6\text{H}_{10}\text{O}_5]_n$ . \*S.G. 1.25-1.45.

**Occurrence.**—Cellulose is the basal substance of the skeleton of plants, and indeed may be said to constitute the framework of the vegetable world. The problem of its origin is as much physiological as chemical. It does not appear to be formed as the immediate product of the synthetical action of the cell upon carbonic anhydride and water, but to arise directly from starch, sugar, and other carbohydrates, through the intervention of the cell protoplasm. The mechanism of this transformation, as well as the inverse conversion of cellulose into the simpler carbohydrates, has not been elucidated, but is assumed on physiological grounds to be of the simplest character. There is nothing in this assumption which contravenes the evidence afforded by the chemical relationships of the carbohydrate group, which are likewise simple.

Adapting itself to the infinite variety of structure and function presented by plant tissues, cellulose occurs in multitudinous forms; and in any given structure is subject to differentiation, modification, or variation of elaboration within very wide limits. The scope of this

article, however, precludes such a treatment of the subject as would deal with lesser variations, and we shall therefore confine our attention to those celluloses which constitute the fully elaborated plant fibres. Plant tissues seldom if ever consist of pure cellulose but contain besides other products of growth, either mechanically bound up with the tissue, and therefore frequently removable by mechanical means and by the action of simple solvents, or chemically united to the cellulose; combinations of this latter kind constitute the compound celluloses, and are only resolved by a chemical process.

**Preparation.**—The isolation of pure cellulose depends upon its relative insusceptibility of chemical change. The general method of preparation from raw fibrous materials consists in exposing the moist fibre or tissue to the action of chlorine gas or bromine-water in the cold and subsequently boiling in a dilute alkaline solution; repeating this treatment until the alkaline solution no longer dissolves anything from the tissue or fibre. The cellulose is then washed with a dilute acid, water, alcohol, and ether, and dried.

**Properties.**—Obtained in this way, or by the ordinary process of bleaching from cotton or linen (flax), or in the form of Swedish filter paper, the typical cellulose is a white substance more or less transparent, retaining the microscopic features of the raw fibre.

The elementary composition is expressed by the percentage numbers (F. Schulze):

C	44.0	44.2
H	6.4	6.3
O	49.6	49.5

or by the corresponding empirical formula  $\text{C}_6\text{H}_{10}\text{O}_5$ . These numbers represent the composition of the dry and ash-free cellulose. Nearly all celluloses contain a certain proportion, however small, of mineral constituents<sup>2</sup> and the union of these with the organic portion of the fibre or tissue is of such a nature that the ash left on ignition preserves the form of the original. It is only in the growing point of certain young shoots that the cellulose tissue is sometimes found free from mineral constituents (Hofmeister). The proportion of hygroscopic moisture, which is an essential constituent of cellulose under ordinary atmospheric conditions, varies from 7 to 9 p.c.; the mean variation due to variations in the hygrometric state of the air is about 1 p.c.

Cellulose is insoluble in all simple solvents; it is dissolved by certain reagents but only by virtue of a preceding constitutional modification. The most remarkable solvent of cellulose is cuprammonia (Schweitzer's reagent) in which it dissolves without essential modification, being recovered by precipitation in a form which is chemically identical with the original (Erdmann, *J. pr.* 76, 385), though differing in being amor-

<sup>1</sup> Cellulose in its earlier stage of elaboration has no action upon light, but with age it acquires the property of double refraction. This action is independent of the state of aggregation of the cellulose and is therefore an essential property of the substance itself (Sachs, *Exp. Phys. d. Pflanzen*, p. 398).

<sup>2</sup> The inorganic constituents of bleached cotton amount to 0.1-0.2 p.c. of its weight. In the manufacture of the so-called Swedish paper, the proportion is reduced by special treatment of the cellulose with acids.

phous. This reagent has been employed in a variety of forms, a fact which explains the discrepancies in the statements as to the solubilities of the various celluloses in cuprammonia. The following methods of applying the reagent are to be recommended.

The substance to be operated upon is intimately mixed with copper turnings in a tube which is narrowed below and provided with a stopcock. Strong ammonia is poured upon the contents of the tube and after standing for some minutes is drawn off and returned to the tube; the operation is several times repeated until the solution of the substance is effected.

Perhaps the most convenient solution, though not so effective in all cases as the former, is that prepared by dissolving ppd. cuprio hydrate in ammonia. In preparing the reagent in this way it is important that the hydrate should be thoroughly washed, preferably out of contact with the air, before dissolving in the strong aqueous ammonia. Cotton is rapidly dissolved by this solution. The soluble compound formed is represented by Mulder as  $(C_6H_{10}O_5)_2Cu(NH_3)_2O$ . It has been doubted whether this compound exists actually dissolved in the viscous solution; an investigation of the osmotic properties of the liquid, however, shows it to be a true solution (Cramer). From an extended investigation of the optical properties of the solution Béchamp concludes that the solution of the cellulose is not simple but is accompanied by progressive molecular transformations, the optical activity (dextrorotatory) of the products increasing to a maximum corresponding to a condition of equilibrium ultimately attained (*C. R.* 100, 117, 279, 368).

The soluble bases (NaOH, KOH) added to the solution give blue gelatinous ppds. having the composition  $(C_6H_9O_4)_2CuM^+O$ . Digested with finely divided lead oxide the solution yields the compound  $C_6H_9O_4.PbO$ . Cellulose is repptd. as a gelatinous hydrate, on the addition of acids, as well as of many neutral bodies such as alcohol, sugar, and common salt, or even on largely diluting with water and allowing to stand. The pp. dried *in vacuo* is obtained as a transparent mass resembling gum-arabic. On digesting the ammonia-cupric solution upon metallic zinc, this metal pps. the copper, replacing it in the solution and producing the corresponding ammonia-zinc solution of cellulose, which is colourless. The property of cellulose of being dissolved by cuprammonia receives an important technical application. A sheet of paper left for a short time in contact with the cuprammonia, so that the constituent fibres are superficially attacked, and then passed between rollers and dried, becomes impervious to water and its cohesion is not affected at the boiling heat. Two sheets thus treated adhere firmly together, and with a sufficient number, artificial boards are produced. A variety of materials are now produced in this way, on the manufacturing scale, useful for roofing and other purposes (*C. R. A. Wright, Journ. Soc. Chem. Ind.* 1884, p. 121).

**Reactions.**—Cellulose has already been spoken of as a comparatively inert substance, and its characteristic reactions are consequently few. One of these is available for its identification and is chiefly used in the microscopical exami-

nations of tissues: this is its reaction with iodine. The reaction, although similar to that of starch, differs in requiring for its determination the presence of an auxiliary (dehydrating) reagent such as sulphuric or phosphoric acid or zinc chloride. The most effective solution is prepared in the following way: zife is dissolved to saturation in hydrochloric acid and the solution evaporated to the sp. gr. 2.0; to 90 pts. of this solution are added 6 pts. potassium iodide dissolved in 10 pts. water, and in this solution iodine is dissolved to saturation. By this reagent cellulose is coloured instantly a deep blue or violet.

**COMPOUNDS OF CELLULOSE.**—Cellulose is generally inactive towards compounds contained in dilute aqueous solution; hence its extensive employment in the filtration of solids from solutions. Nevertheless it exhibits a tendency to incipient combination even with acids and alkalis (Mills, *C. J.* 43, 153); with metallic salts it forms compounds of sufficient stability to cause their removal from solution, but the combination is of an indefinite and unstable order (Erdmann, *J. pr.* 76, 385). (*Cf.* Gladstone, *J. pr.* 56, 217; Müller, *Fr. J.* 84; O'Shea, *C. J. Proc.* 1, 206.) Certain carbon compounds, such as the organic astringents, and many of the colouring matters natural and artificial, unite with cellulose to form compounds of various orders of stability; of these we would more particularly instance amongst others many of the derivatives of diphenyl which possess a specific power of direct combination with cellulose. Although such combinations are of great technical importance, being the foundation of the arts of dyeing and printing they are not sufficiently systematised to deserve more than this passing notice. On the other hand some of the substitution-compounds of cellulose with acid radicles are both definite and stable.

**Acetyl-cellulose.**—The tri-substituted compound  $C_6H_7(C_2H_3O_2)_3$  is formed by heating cellulose with 6-8 times its weight of acetic anhydride at 130°, and separates as a white flocculent pp. on diluting the syrupy product. Tri-acetyl-cellulose is insoluble in alcohol and in ether, and is soluble in glacial acetic acid. It is saponified by boiling with alkaline solutions, the cellulose being regenerated. No derivative containing more than three acetyl groups has been obtained; but a mixture of the mono- and di-acetyl cellulose is formed by treating cellulose with only twice its weight of acetic anhydride, the formation of these bodies being unattended by their solution.

**Cellulose nitrates.** (*Pyrroxylin*—*Nitrocellulose*.)—Whenever cellulose in any form is brought into contact with strong nitric acid at a low temperature, a nitro-product or nitrate is formed. The extent of the nitration depends upon the concentration of the acid, upon the duration of its contact with the cellulose, and on the state of the physical division of the cellulose itself. The first investigation of these substances dates from 1838, when Pel'ero showed the identity of several of these products obtained from paper, linen &c. and starch. Knop and also Kanarsch and Heeren found that a mixture of sulphuric and nitric acids also formed nitrate of cellulose; and still later (1817) Millon and Gaudin employed a mixture of sulphuric

acid and nitrate of potash and soda, which they would have the same effect. Although gun-cottons or pyroxylines are generally spoken of as nitro-celluloses, they are more correctly described as cellulose nitrates, since they have not been found to yield amido-bodies on reduction with nascent hydrogen. The following are the general properties of these compounds (Eder):

- 1) When warmed with alkaline solutions, nitric acid is removed in varying quantities, dependent upon the strength of the solution employed.
- 2) Treatment with cold concentrated sulphuric acid expels almost the whole of the nitric acid.
- 3) On boiling with ferrous sulphate and hydrochloric acid, the nitrogen is expelled as nitric oxide; this reaction is used as a method of nitrogen estimation in these bodies.
- 4) Potassium sulphhydrate, ferrous acetate, and many other substances, reconvert the nitrates into cellulose.

Several well-characterised nitrates have been obtained, but it is a matter of difficulty to prepare any one in a state of purity and without admixture of a higher or lower nitrated body. The following have been described under a nomenclature having reference to a  $C_n$  formula:

**Hexa-nitrate.**— $C_{12}H_{11}(NO_3)_6O_2$  (gun-cotton). Prepared by treating cotton with a mixture of  $HNO_3$  (S.G. 1.5) 3 parts, and  $H_2SO_4$  (S.G. 1.84) 1 part, for 24 hours, at a temperature not exceeding  $10^\circ$ ; 100 parts of cellulose yield about 175 of the compound (calc. 183). Insoluble in alcohol, ether, or mixtures of both, and glacial acetic acid; with acetone it forms a jelly and is slowly dissolved. It is the most explosive of the series igniting at  $160^\circ$ – $170^\circ$ . Mixtures of sulphuric acid and nitre do not give this nitrate (Eder). Ordinary gun-cotton may contain as much as 12 p.c. of nitrates soluble in ether-alcohol; the hexa-nitrate seems to be the only one quite insoluble in this menstruum.

**Penta-nitrate.**— $C_{12}H_{11}(NO_3)_5O_2$ . This composition has been very commonly ascribed to gun-cotton.\* It is impossible to prepare it in a state of purity by the direct action of the acid on cellulose. It is prepared by dissolving the hexa-nitrate in nitric acid at  $80^\circ$ – $90^\circ$ , cooling to  $0^\circ$ , and adding concentrated sulphuric acid, by which the penta-nitrate is precipitated; after mixing with a large volume of water and washing the precipitate with water and alcohol, it is dissolved in ether-alcohol and finally re-precipitated by water. This nitrate is slightly soluble in acetic acid, nearly insoluble in alcohol containing only a small proportion of ether. Strong potash solution converts it into the di-nitrate.

**Tetra- and tri-nitrates** (collodion pyroxyline) are generally formed together when cellulose is treated with a more dilute acid at a higher temperature and for a shorter time than in the case of the hexa-nitrate, e.g. 4 vols.  $HNO_3$  (1.38), 5 vols.  $H_2SO_4$  (1.84) at  $65^\circ$ – $70^\circ$  for 5–10 minutes. They are freely and equally soluble in ether-alcohol, acetic ether, and mixtures of acetic acid and wood spirit, or alcohol, and are therefore inseparable. They are insoluble in pure alcohol, ether, or acetic acid. On treatment with concentrated nitric and sulphuric acids they are converted into the higher nitrates. Potash and ammonia convert them into the dinitrate.

**Di-nitrate**  $C_{12}H_{11}(NO_3)_2O_2$  is formed as already indicated, and also by the action of hot dilute nitric acid on cellulose. Freely soluble in ether-alcohol, acetic ether, acetic acid, wood spirit, acetone, and absolute alcohol. The further action of alkalis on the dinitrate results in a complete resolution of the molecule.

The cellulose nitrates have generally much stronger absorption-affinities for colouring matters than the celluloses. They are much less susceptible of attack by acid oxidants than cellulose itself, and are therefore used in the filtration of solutions containing e.g. chromic acid, permanganates, and, of course, nitric acid of any degree of concentration. Nitric acid of S.G. 1.42 has a remarkable toughening action upon filter paper: the modification is effected by simple immersion, and the paper so treated is increased in strength tenfold, undergoing at the same time a contraction amounting, in circles, to about  $\frac{1}{3}$  diameter. The cellulose so treated contains no nitrogen (Francis, *C. J.* 47, 183).

**Cellulose and sulphuric acid.**—Cellulose is disintegrated and dissolved by the concentrated acid to a colourless solution. The products are sulphates of a series of compounds of which the celluloses and the dextrins may be regarded as the extreme terms. They are easily isolated in the form of Ba salts. The composition of the sulphates may be expressed by the general formula  $C_{12}H_{11}O_{2n-1}(SO_3)_n$ . The variations in composition and in physical properties are functions of the temperature ( $5^\circ$ – $33^\circ$ ) and duration of the action. The limits of specific rotation of these sulphates are  $[\alpha]_D = -3.65$  and  $+72.99$ . These ethereal salts are entirely decomposed by boiling with alcohol: the resulting carbohydrates may be regarded as the corresponding alcohols. In composition and properties (e.g. their reactions with iodine) they constitute an extended series, beginning with soluble celluloses and terminating in achrodextrin (Hönig and Schöberl, *M.* 7, 455). While it is impossible to determine the mechanism of these successive resolutions of the cellulose molecule with the precision attainable where such changes may be reversed, and therefore completely studied, they certainly establish the typical connection of the celluloses with the simpler carbohydrates, and in a much more complete way than the coincidence of empirical formulae.

Prior to the researches above detailed the initial terms of the transition series had been similarly obtained and described under the term *Amyloid*, a term selected to indicate their resemblance to starch.

A practical application of the reaction of cellulose with sulphuric acid is found in the manufacture of *parliament paper*. The process consists in the rapid passage of the paper through the strong acid (S.G. 1.5–1.6) followed by copious washing. The result may be described as a superficial conversion of the cellulose into amyloid, whereby it acquires the properties which have obtained for it the designation in question (cf. Hofmann, *A.* 112, 243).

**Cellulose and chlorine.**—Dry chlorine has no action upon cellulose; the presence of water determines an indirect oxidising action, but there is no direct combination of cellulose with

chlorine. By heating cellulose nitrates with phosphoric pentachloride and oxychloride at 200° and evaporating the excess of the reagents at 170°, a viscous liquid is left, miscible with alcohol and ether, which appears to be composed of, or to contain, a chloride of cellulose or a cellulose derivative (Baeyer, *B. 2*, 54). Bromine is without action upon cellulose: specimens left for several months in contact with strong bromine-water were not sensibly attacked (H. Müller, *Pflanzenfaser*, p. 27; cf. Franchimont, *R. T. C.* 2, 91).

**Cellulose and Oxygen.** *Oxycelluloses.*—Two of these compounds or series of compounds have been described.

(a) *Oxy-cellulose* (Witz, *Bull. Rouen*, 10, 416; 11, 189) is formed by the action of solutions of the hypochlorites upon cellulose. Exposed to the action of a solution of bleaching powder (5 p.c.) for 24 hours, the fibre is converted into a friable modification having the composition C 43.0, H 6.2, O 50.8. Other oxidising agents produce similar results; even by exposure to air and light cellulose is slowly converted into these oxidised derivatives. Their formation is accompanied by molecular resolution, as is shown by their reducing action upon alkaline copper solutions: the product giving this reaction is dissolved by alkalis to a yellow solution. These oxycelluloses have a strong attraction for basic colouring matters: also for vanadium compounds, attracting these from a solution containing so minute a quantity as 1 pt. in 1,000,000,000. Upon this property a method has been founded for the quantitative estimation of minute traces of vanadium in aqueous solution (Witz a. Osmond, *Bull. Rouen*, 14, 30). The study of these oxycelluloses is of great importance to the manufacturer of textile materials.

(b) *Oxy-cellulose*  $C_{12}H_{10}O_{10}$  (Cross a. Bevan, *C. J.* 43, 22) is the residual product (insoluble) of the prolonged digestion of cellulose with nitric acid (20–30 p.c.) at 90° C. On washing with water to remove the acid the substance gelatinises. It dries to a horny colourless mass. It is characterised by its reaction with sulphuric acid: on gently warming it dissolves with development of a bright pink colour, the reaction resembling that of mucic acid, to which, on other grounds, it is probably related. A fresh preparation, treated with a mixture of nitric and sulphuric acids, dissolves, and on pouring into water the nitrate  $C_{12}H_{10}(NO_3)_2O_{10}$  separates as a white flocculent pp.

**Chromic acid.**—Cellulose treated with potassium dichromate in presence of acetic acid is converted into glucose, dextrin, and formic acid. Permanganates under the same condition effect a similar decomposition.

**Chromic anhydride** in presence of sulphuric acid decomposes cellulose rapidly and completely, the carbon being entirely converted into the gaseous compounds CO and CO<sub>2</sub>. It has been proposed to apply this to the quantitative estimation of carbon in celluloses and cellulosic mixtures (Cross a. Bevan, *C. J.* 52, 207).

**Alkaline oxidations.**—The permanganates and hypochlorites in presence of alkalis oxidise cellulose to a syrupy mixture of acids of the pectic series (H. Müller, *Pflanzenfaser*, v. also *S. C. I.* 3, 206, 291). Fused with potassium

hydrate the cellulose is oxidised to oxalic acid, malic acid being obtained as an intermediate product.

**Electrolytic oxidants.**—The nascent oxygen and other electronegative ions liberated in the electrolysis of various saline solutions have a very powerful action upon cellulose. These actions have been made the subject of interesting researches by F. Goppelsroeder (*D. P. J.* 254, 42).

**Cellulose and Hydrolytic Agents.**

(1) *Dilute acids.* A large number of acids, organic as well as mineral, attack cellulose, producing hydration changes, attended by disintegration of the fibre. The action is gradual at ordinary temperatures, and is of course accelerated by applying heat. The study of these actions is of the first importance to the cellulose technologist (Mirard, *C. R.* 81, 1105; Cross a. Bevan, *S. C. I.* 1885; Crookes, *Handbook of Dyeing and Calico-printing*, p. 19).

It is worthy of note here that the cellulose isolated from grass and hay, and many others less highly elaborated than the celluloses which we are at present considering (cotton and linen), are decomposed on boiling with dilute mineral acids with formation of furfural.

(2) *Alkalis.*—Dilute solutions of the alkalis are without sensible action upon cellulose, even at temperatures considerably above the boiling point: when, however, oxidising conditions are superadded, molecular resolution sets in. The joint action of calcium hydrate and air at the boiling temperature is especially powerful, oxy-cellulose being produced (Witz, *loc. cit.*). Concentrated solutions of the alkalis (NaOH, KOH) at ordinary temperatures act in a very remarkable way upon cellulose. There appears to be a 'molecular' combination of the reagents in the proportion  $C_{12}H_{10}O_{10}.Na_2O$  (Mercer) which however is easily resolved by washing with water. But the characteristics of the fibre and the fibre substance are found to have undergone a permanent modification. There is a considerable shrinkage in linear dimensions: in cotton fabrics treated with caustic soda solution of S.G. 1.225 this amounts to 25 p.c. The corresponding modifications in microscopic features have been investigated by Crum (*C. J.* 1863), the changes being found similar to those which take place in the ripening of the fibre in the plant, viz. from a flattened tube with large central cavity, to a thick-walled cylinder with small lumen. The chemical change produced is, so far as has been ascertained, entirely one of hydration, and it is remarkable that the only evidence of the change is the increased capacity for hygroscopic moisture. This amounts to 5 p.c. of the weight of the cotton, the proportion calculated for the formula  $C_{12}H_{10}O_{10}.H_2O$  being 5.5 p.c. From this fact we may also infer that the normal attraction of cellulose for atmospheric moisture is a residual manifestation of the molecular combinations which are seen in the multitudinous hydrates of cellulose found in, or constituting, growing tissues. Mercer, who appears to have first investigated these phenomena, further found that the addition of hydrated oxide of zinc very much increased the action of the caustic solution: thus a solution of sodium hydrate of S.G. 1.100, which is without marked action, is rendered very active by

the addition of the oxide in the proportion  $\text{ZnO} : 2\text{Na}_2\text{O}$ . He also found that the actions were favoured by low temperatures (*v. Life of John Mercer* by E. A. Parnell, London, 1886).

By these characteristics the hydration phenomena in question are seen to be closely related to those attending the action of the Schweitzer reagent (*supra*). The more powerful action of the latter we must refer either to the specific action of the ammonia upon the condensed aldehydic molecules of which cellulose appears to be constituted, or to the particular relationship of the molecular weight of the cuprammonia in solution to that of the cellulose or cellulose hydrate which it forms.

The action of concentrated solutions of zinc chloride is similar to that of the alkaline hydrates above hydrates. It is remarkable on the other hand that a saturated solution of zinc nitrate is without action (Mercer).

(3) *Water*.—Heated in contact with water, cellulose is attacked at  $160^\circ$ , but not below  $150^\circ$  (Scheurer n. Grosseteste, *Bull. Mulhouse*, 1883, 62-85). Heated at  $200^\circ$  in contact with water in sealed glass tubes it is fundamentally resolved, being converted into highly coloured products, insoluble for the most part, with a small proportion of soluble derivatives amongst which are furfural and pyrocatechol (Hoppe-Seyler, *B. 4*, 15).

(4) *Ferments*.—There are, it can scarcely be doubted, endless transformations of cellulose determined by the so-called soluble ferments, though but few have been investigated. The soluble ferment of the foxglove is stated to convert cellulose into glucose and dextrin (Kosmann, *Bl. 2* 27, 246). The fluid from the vermiform appendix of the rabbit has also been found to digest cellulose with liberation of marsh gas and formation of a soluble compound which reduces cupric oxide in alkaline solution.

**Proximate Syntheses of Cellulose.**—Transformations of the soluble carbohydrates into cellulose, which we may regard as a proximate synthesis of this body, are, as already stated, an important feature in the life of plants. The mechanism of these changes has been thus far but slightly studied, and they are of a kind to elude chemical investigation. Of those which have been studied we may notice (a) There is a change set up 'spontaneously' in beet juice which results in the formation of a hard white substance, having the properties of cellulose. On transferring these lumps to a solution of pure cane sugar, a further transformation of the saccharose into the same substance is brought about. At the same time there is produced a gummy substance which is pptd. by alcohol as a white caoutchouc-like substance of the same composition as cellulose but swelling up with water and otherwise differing in its physical properties from cellulose. This latter derivative is also formed by the action of diastase upon a solution of saccharose. A similar transformation takes place under the influence of certain fatty seeds, *e.g.* those of rape and colza, and it is probable that the formation of cellulose from saccharose in the plant takes place under the influence of ferments similar to those above described (Durin, *C. R.* 82, 1108).

(b) More recently A. Brown has investigated

the formation of cellulose by the 'vinegar-plant,' growing in solutions of the carbohydrates, *e.g.* dextrose in yeast-water. The cells elaborate an extra-cellular film, which acts as a cell-collecting medium, and which possess, therefore, a two sided activity, *i.e.* the property above mentioned, in addition to their strictly fermentative activity. The cellulosic film in question was found to contain 50-60 p.c. pure cellulose. It is noteworthy that in a solution of levulose the growth of the 'plant' is unattended by fermentative action, 33 p.c. of the substance being on the other hand transformed into cellulose (*C. J.* 48, 432).

#### OTHER FORMS OF CELLULOSE.

We cannot attempt to enumerate the multitudinous varieties of cellulose which the plant world presents. Some of these, when isolated in the pure state, resemble the typical cellulose above described, *e.g.* the cellulose of hemp and rhea. Others, especially such as require a drastic process of resolution, *e.g.* the cellulose isolated from jute and wood by the chlorination method (*infra*), resemble rather the (a)-oxycelluloses. Thus jute cellulose ( $3\text{C}_6\text{H}_7\text{O}_2\text{H}_2\text{O}$ ) reduces cupric oxide in alkaline solution, and is much more susceptible of degradation by hydrolytic reagents than those of the cotton type. Cellulose from pinewood is similar in composition and properties.

Cellulose from esparto and straw, isolated by treatment of the plant substance with alkaline solutions boiling under pressure—which are amongst the most important of the staple materials of the paper-maker—are distinguished by their reaction with aniline salts, being coloured a deep pink on boiling with solutions of these compounds. Many of the celluloses are decomposed on boiling with dilute acids with formation of furfural and formic acid: hay cellulose yields under certain conditions a volatile crystalline body, which appears to be a furfural derivative, but is still under investigation.

It may be mentioned here that the term cellulose is applied by plant physiologists and agricultural chemists to substances which would not come under the definition, upon which this article is based, of cellulose as the (white) insoluble residue which survives the exhaustive treatment of plant substances alternately with chlorine, bromine, or oxidising agents, and boiling alkaline solutions.

**Animal cellulose.**—The mantles of the Pyrosomide, Salpide, and Phallusia mammillaris, freed from chondrogen by boiling in a Papin's digester and further purified by prolonged boiling with potash solution, yields a residual substance which not only has the ultimate composition of cellulose, but has identical properties, *e.g.* dissolves in cuprammonia, is converted by nitric acid into an explosive nitrate soluble in ether (Schäfer, *A.* 160, 312). According to Virchow cellulose is found in degenerated human spleen and in certain parts of the brain (*C. R.* 37, 492, 860).

#### COMPOUND CELLULOSES.

Plant tissues, always containing a proportion of cellulose more or less large, frequently contain other constituents so intimately united to

the cellulose as to mask its reactions. From the circumstances of their occurrence and formation it is not to be expected that the line can be sharply drawn between mixtures and combinations of cellulose with non-cellulose constituents of either fibres or tissues. Frémy (*Ann. Agronomiques*, 9, 529) recognises the existence of the following compounds distinguished from cellulose chiefly by their different behaviour to hydrolytic reagents and cuprammonia; (1) *Fibrose*, constituting the membranes of wood cells; (2) *Paracellulose*, constituting the membrane of the pith and medullary rays, and (3) *Vasculose* constituting the membranes of the vessels. The value of this somewhat arbitrary classification is questionable (Sachse, *Farbstoffe, Kohlehydrate*, &c., p. 150), and the distinctions which it seeks to establish have not been generally recognised. On the other hand, there are certain groups of substances widely distributed throughout the plant world, which, while they have certain features in common with the celluloses, are sufficiently distinct to admit of chemical classification apart from them. Generally speaking, these substances are made up of a cellulose and a non-cellulose portion, the latter conferring the special features of distinction. The compound cellulose thus constituted is resolved, by treatment with reagents according to the methods to be described, into cellulose or a cellulose residue on the one hand, and soluble derivatives of the non-cellulose on the other. Of these groups we shall consider typical members.

The following are the compound celluloses sufficiently characterised to warrant special description under class names: the nomenclature of these compounds is explained by their characteristic resolutions.

#### *Pectocelluloses*

Resolved by hydrolysis (alkalis)  
into

Pectic acid and cellulose.

Type: Raw flax

(Kolb, *Bull. Mulh.* 1868, *A. Ch.* [4] 14, 348).

#### *Lignocelluloses*

Resolved by chlorination  
into

Chlorinated deriva.:  
Aromatic } and cellulose.  
Soluble in alkalis }

Type: Jute

(Cross & Bevan, *C. J.* 41, 90).

#### *Adipocelluloses*

Resolved by oxidation  
(Nitric acid)  
into

Similar deriva.:  
as by the oxidation } and cellulose.  
of the fats }

Type: Cuticular tissue of leaves and fruits  
(Frémy, *C. R.* 48, 667; Sachse, *Farbstoffe*, &c.).

**Pectocelluloses.**—The purified bast of a Russian flax investigated by Kolb was found to have the aggregate composition:

C 43.7  
H 5.9  
O 50.4.

The non-cellulose constituent is therefore a substance of lower carbon percentage than cellulose. From its yielding pectic acid on boiling with alkalis, it is obviously a substance allied to pectin. Since the fibre yields about 20 p.c. of its weight of the acid derivative we infer independently that it is a substance containing approximately 41 p.c. carbon, which confirms the view of its constitution above expressed. Many other plant fibres are made up of or contain pectocelluloses (Welster, *C. J.* 43, 23); pectic derivatives were identified by Schunck in the products of the action of boiling alkaline solutions upon raw cotton (*Proc. Manchester Lit. Phil.* [3] vol. iv).

The cellular tissue of a large number of fruits, e.g., the apple and pear, and roots, e.g., turnips and carrots, is composed of pecto-celluloses.

**Lignocelluloses.**—The course of lignification in plants is marked by profound alterations in the physical properties of the tissues undergoing this modification; the tissues lose their elasticity, become coloured from grey to brown, and the substance of the tissues manifests the chemical properties about to be described.

**Jute.**—Aggregate percentage composition: C. 47.0-48.0, H. 5.9-5.7, O. 47.1-46.3 ( $C_{12}H_{15}O_8$ ). It may be regarded as composed of

Non-cellulose (Lignin)  $C_{10}H_8O_4$  (55.5 p.c. C) 25 p.c.  
and Cellulose  $C_6H_{10}O_5$  (44.4 " ) 75 "

though the cellulose isolated from the fibre by chemical resolution differs in composition as already stated from normal cellulose, appearing rather as an oxycellulose. The mineral constituents of the raw fibre (purified) vary from 0.5 to 2 p.c. of its weight; the hygroscopic moisture from 10-12. Attacked by concentrated solutions of the alkalis similarly to cotton; freely soluble in cuprammonia, but is incompletely precipitated on acidifying; the body remaining in solution gives the reactions of the original substance, and may, therefore, be regarded as a hydrated modification. Jute combines freely with the organic astringents (tannins) and the majority of aromatic colouring matters. It is coloured a bright yellow by solutions of salts of aniline and other aromatic bases. This reaction is probably due to a product of oxidation, *sic*, it does not take place with jute which has been boiled for some time in solutions of sulphuric acid. It is coloured brown by iodine solutions. Moistened with a solution of phlor gluc. and treated afterwards with hydrochloric acid it gives a deep red colouration; with pyrol also in presence of hydrochloric acid it gives a deep carmine colour. A mixture of sulphuric and nitric acids nitrates the fibre, the g in weight being approximately equal to that of cellulose under the same conditions. The products are orange-coloured and are soluble in acetone. Like the cellulose nitrates, they give no amide derivatives on reduction. Iodine is absorbed by the fibre, the quantity taken up being constant under constant conditions; the resulting compound is not more stable than the iodide of starch. This

reaction may be made use of for the quantitative estimation of the lignocelluloses in cellulosic mixtures. Bromine attacks the fibre in presence of water, forming ill-defined compounds which are dissolved by alkaline solutions. The operation once or twice repeated eliminates the whole of the non-cellulose; the resulting cellulose amounts to 72-75 p.c. of the weight of the fibre. Chlorine does not act upon the dry fibre, even when the temperature is raised to 160°, but in presence of water combines rapidly at ordinary temperatures with evolution of heat. The chlorinated derivative is yellow coloured; it is soluble in alcohol, and from the solution water precipitates the compound  $C_{10}H_{14}Cl_2O_5$ , as a yellow flocculent mass. This compound gives a characteristic magenta colouration with sodium sulphite solution similar to that of mairongallol<sup>1</sup> (Webster, *C. J.* 45, 205). It dissolves in solutions of the caustic alkalis with a brown colour, evolving the characteristic odour of the chloro-quinones. It yields chloropierin on distillation with nitric acid. Fused with potassium hydrate it yields protocatechic acid. It is therefore an aromatic derivative, and appears to be allied to the trihydric phenols. The chlorinated fibre when boiled with sodium sulphite solution is entirely resolved into cellulose, and soluble derivatives of the non-cellulose or lignin constituent. This constitutes the simplest and most rapid method of cellulose estimation in the fibre. The proportion of cellulose obtained is somewhat higher than by the bromine method (75-78 p.c.) and is further increased by preventing rise of temperature in the chlorination.

Digested with dilute nitric acid at 80° jute is resolved directly into cellulose (oxycellulose) oxalic and carbonic acids and a peculiar acid derivative of the lignin constituent. This body has the formula  $C_{10}H_{10}(NO_2)_2O_5$ ; it is of an intense yellow colour, and dyes the animal fibres to a similar shade. It forms salts with the earthy bases ( $C_{10}H_{10}(NO_2)_2O_5.M'$ ) which are precipitated by alcohol from aqueous solutions in the form of bright yellow floccs.<sup>2</sup>

**Hydrolytic agents.**—Jute and the lignocelluloses generally are much more susceptible of hydrolysis than the simple cellulose. The dilute acids effect a simple hydrolysis at 80°, i.e. the portion dissolved has the same composition and properties as the original; on raising the temperature to boiling, furfural is obtained in considerable quantity. Boiling dilute alkalis effect a simple hydrolysis. When the hydrolysis is complicated by the introduction of either reducing or oxidising conditions, resolution into cellulose and non-cellulose (soluble derivatives) is determined. Thus sulphurous acid, the bisulphites, and the normal sulphites (alkaline) attack and resolve the lignocelluloses when heated with their solutions under pressure. The temperatures necessary for efficient resolution,

i.e. for the isolation of cellulose, are with sulphurous acid (7.5 p.c.  $SO_2$ ) 90°-100°, with bisulphites (4 p.c.  $SO_2$ ) 150°, with normal sulphites (4 p.c.  $SO_3$ ) 170°-180°; the increase of temperature corresponding with the diminution of hydrolytic power by progressive neutralisation of the acid. The hydrolysis is aided by combination of the reagents with the soluble derivatives, which prevents the reversal of the action at the high temperature, which would otherwise occur. In heating with solutions of the caustic alkalis under pressure, a high temperature is necessary for complete resolution; a considerable proportion of the reagent is necessary for combining with the products, which under the oxidising conditions are of an acid nature. These facts are of importance in the preparation of cellulose from lignocelluloses, which is now a widely extended industry (*Forestry Exhibition Reports*, Edinburgh, 1885).

**Animal Digestion.**—It has long been known that the urine of the hepivora contains hippuric acid as a normal constituent, and it has been shown that the benzoyl radicle necessary to form this body is a product of the digestion of lignocellulose (Meissner). Since the lignocellulose molecule contains no aromatic compounds in the strict sense of the term (Stutzer, *B. 8*, 575) the process of digestion must effect the conversion.

**Decomposition by Heat.**—**Cumulative Resolution.** The celluloses burn in the air with a quiet luminous flame. When heated out of contact with the air they are completely resolved into gaseous and volatile products on the one hand, and a residual black mass, containing a high percentage of carbon. Regarding these carbonaceous substances as the products of condensation of cellulose molecules with elimination of water, the process may be viewed as, in the main, one of cumulative resolution by dehydration (Mills, *P. M.*, June, 1877); the cumulate containing hydrogen and oxygen in chemical union with carbon is still in every sense a compound; taking into consideration, at the same time, its approximation in appearance and properties to the element itself it may be termed a *pseudo-carbon*.<sup>3</sup> Dehydrating reagents effect similar resolutions, the lignocelluloses undergoing condensation more readily than the celluloses. The tendency to carbon accumulation which is the main feature of these resolutions is well marked in the vast series of natural products of the decay of cellulosic tissues, from humus to the coals. Though not of pyrogenic origin they nevertheless deserve mention in this connection from considerations of general resemblance.

It is noteworthy that the products of chlorinating alkali substances (Sestini, *Gaz. It.* 1882, 292) are closely similar to those obtained from the lignocelluloses. Similar products are also yielded by the cannel coals.

**Other forms of Lignocellulose.** Two other varieties of lignocellulose deserve mention, viz. *glycolignose*,  $C_{20}H_{30}O_{21}$ , the substance of fir woods '*glycodrupose*,'  $C_{20}H_{30}O_{20}$ , the substance of the stony concretion of pears (Erdmann, *A.* 188, 1; *Suppl.* 5, 223; Bente, *B. 8*, 476; Sachsse, *Farbstoffe*, 151). On boiling with dilute

<sup>1</sup> According to Hantzsch & Schuster (*M.* 20, 2033), mairongallol is a species of condensed quinone chloride—the characteristic molecule being derived from quinone by replacement of one of its typical O atoms by  $Cl$ , the aromatic linking being at the same time partially resolved. Such a view accords equally well with the properties of the derivative in question.

<sup>2</sup> It is worthy of note that the addition of urea to the dilute acid considerably modifies its action, which becomes one of simple hydrolysis as in the case of sulphuric and hydrochloric acids (*ibid.*).

<sup>3</sup> *Phil. Mag.*, 1882, 335.

hydrochloric acid these compounds are said to be resolved into a sugar and an insoluble residue, lignose =  $C_6H_{10}O_5$ , and drupose =  $C_{10}H_{16}O_4$ , respectively. On comparing these formulae with those of the original substances, the differences are so slight as to be negligible. The action of the acid is probably therefore one of simple hydrolysis. The reactions of these substances are also in other respects identical with those of the jute substance. Although therefore differing from the ligno-cellulose, above described, in ultimate composition, they are essentially of the same order of compounds.

**Crude fibre.** This term is applied by agricultural chemists to the residual product of the treatment of fodder plants with boiling solutions of certain acids and alkalis, applied successively. The process is a crude imitation of the process of digestion in the animal, and the results which it yields are of purely empirical value. Crude fibre will be found on examination, in most cases, to be a ligno-cellulose and to be further resolved by chlorine in the manner indicated.

**ADIPOCYELLOUSES, Cork and Cuticular Tissue.** From the mode of formation of these tissues it has been concluded, on physiological grounds, as in the case of the lignocelluloses, that they are modified celluloses (Saechse, *Färbstoffe*, &c. p. 153). The ultimate composition of cork is represented by the following percentage numbers: C 65.7, H 8.3, N 1.5, O 24.5. Unlike the lignocelluloses, however, it is by no means a simple or homogeneous substance, but is resolved by the action of mere solvents into a number of proximate constituents, some of which are crystalline. The residue from the action of these solvents may be regarded as the true cork substance. It is resolved by the action of boiling nitric acid (20-30 p.c.) into cellulose on the one hand—only a small proportion (3-5 p.c.), however, surviving so severe a treatment—and a series of fatty acids (or products of their decomposition) such as suberic and adipic acids, on the other; the latter amount to about 40 p.c. of the weight of substance treated. If cork be resolved by treatment with sodium sulphate solution, at 166° a soft mass is obtained preserving the structural features of the original, but which on slight pressure breaks down into a cellular mass. On slight purification this yields a pure cellulose; the proportion obtained being from 9 to 12 p.c. of the original cork. From these resolutions into cellulose, and products of decomposition similar to those obtained from the fats and waxes under similar treatment, the substance of cork has come to be regarded as a compound of such molecules; and this view of its constitution, as well as that of the entire group of substances similar in composition and function, is summed up in the group term Adipocellulose, by which it is proposed to designate them. The cuticular tissues, such as constitute the covering of fleshy fruits and leaves, while similar in many respects, are simpler in composition. When purified they are non-nitrogenous and appear to be homogeneous.

Frémy and Urbain have developed (*C. R.* 100, 19) a somewhat different view of the constitution of these tissues. Taking the protective tissues of the leaf of the agave as the type, in

addition to an interior epidermal layer, which is cellulosic, and is soluble in cuprammonia after treatment with boiling hydrochloric acid, they distinguish the external or true epidermis, which they term Cutose. The substance composing this tissue has the following properties: it is resolved by alkaline saponification into two fatty acids, *oleocutic*  $C_{25}H_{48}O_2$ , a liquid oily body, and *stearocutic*  $C_{25}H_{48}O_2$ , a solid body melting at 76°, soluble in benzene and glacial acetic acid, and slightly soluble in boiling alcohol, the solution gelatinising on cooling. The following numbers give the percentage composition of the original cutose and of the two derivatives.

	Cutose	Oleocutic acid	Stearocutic acid
C	68.4	66.6	75.5
H	8.7	8.2	10.3
O	22.9	25.2	14.2

Whence it is concluded that the molecule of cutose is composed proximately of oleo- and stearo-cutic acids in the molecular proportion of 5:1.

The two derived acids above described are marked by a curious instability or tendency to reversion, passing under certain conditions, notably by exposure of their solutions to light, into modifications closely resembling the original cutose.

With regard to the distribution of cutose in the plant world, while it is the main constituent of the external protective tissues of leaves, fleshy fruits and the stems of annuals, it is found also in the interior tissues, e.g. the bast and fibro-vascular bundles.

These researches are an important contribution to the subject; and while there is no reason to doubt the authors' conclusions in the main, it is probable that they have overlooked the presence of cellulose as a constituent of cutose which occurs as an organised i.e. cellular tissue. We need scarcely observe that the chemistry of these adipocelluloses has been but little investigated.

#### CONSTITUTION OF CELLULOSE.

The physical properties of cellulose throw but little light on the problem of its molecular constitution. We have seen, moreover, that cellulose is chemically inert; its derivative compounds are few, and of these indeed the nitrates alone appear to merit such a description, their formation being unattended by molecular resolution. From their composition and properties we infer the presence of alcoholic OH groups in the cellulose molecule. The gradual resolution by the action of sulphuric acid, through a series of compounds terminating with achroodextrin, indicates a certain constitutional relationship to the simpler carbohydrates of which the latter is a typical representative. The exact mechanism of the resolution not having been elucidated, it is impossible to draw any but the general inference from the products to the original cellulose molecule, viz., that the latter is a complex of molecules resembling these simpler and better known carbohydrates. We also infer that the bond which unites them is one of dehydration, but the exact nature of this bond is for the present entirely conjectural. (For a discussion of the probabilities involved in this problem the reader is referred to a paper by Baeyer entitled

'Wasserentziehung u. ihre Bedeutung für das Pflanzenleben und die Gährung,' B. 3, 63.) That such molecules are to be regarded physiologically as well as chemically, as the proximate constituents of the cellulose molecule, is a conclusion which has perhaps been somewhat prematurely drawn. Its ultimate origin is of course to be traced to the carbonic anhydride and water of the air and soil, the synthesising agencies being the protoplasm and chlorophyll of the plant, aided by the supplies of energy from without. It has been supposed that the mediate source of the vegetable carbohydrates is formic aldehyde, and the recent researches of Loew (B. 20, 141) upon the condensations of this aldehyde have at least confirmed the probability of this supposition. The products of resolution of cellulose, moreover, clearly indicate the presence of aldehydic groups in the molecules. Apart from conjecture, we may, to sum up this brief review, regard the cellulose molecule as a complex of simpler carbohydrate groups, containing alcoholic and aldehydic oxygen (v. also Bowman, B. A. 1887).

The most striking features of the empirical formula of cellulose  $C_6H_{10}O_5$ , are those characteristic of the entire group of carbohydrates, the molecule containing some multiple of  $C_6$  and the hydrogen and oxygen having the ratio 2:1. At present these relationships are merely suggestive of conditions of molecular equilibrium to be elucidated by future investigation.

The prevalence of the  $C_6$  group is remarkable and suggests a relationship to the aromatic group, which is confirmed by the undoubtedly cellulosic origin of the benzene compounds. On the other hand we have no evidence of the existence of closed chains of C atoms in the cellulose molecule, nor have any simple transitions from the one group to the other been as yet discovered. If we turn, however, from the typical cotton cellulose to other forms of cellulose, such as those isolated from growing tissues, we find in the ease with which many of them yield furfural as a product of acid hydrolysis, some evidence of a more complex union of the C atoms, than the normal type usually assumes. Passing on further to the lignocelluloses we find a molecule in the constitution of which a furfural group undoubtedly plays a part, and in which the linking of the C atoms is such as permits a simple transition, in part at least, to products of undoubtedly 'aromatic' composition.

We have, in this brief statement of the evidence which we have upon which to found our views of the constitution of cellulose, endeavoured rather to indicate the main lines upon which the investigation of the problems involved is proceeding, than to draw premature conclusions. The subject will be enormously developed in the future, and will constitute an important foundation of the natural history of the carbon compounds; a department of view of the science which can scarcely as yet be said to be within reach.

#### NOMENCLATURE.

Considerable confusion has been imported into this subject by the indiscriminate employment of the terms, cellulose, lignin, woody fibre, lignose, 'crude fibre,' in describing the

various products, natural and artificial, of which this article treats. The want of uniformity arises from the division of the subject amongst physiologists, agriculturists and chemists. That which we have adopted appears to bring about a certain simplification.

The application of the term cellulose we have already defined and limited. To denominate the compound celluloses, which correspond with the chief modifications of cellulose recognised by physiologists, we use a compound term consisting of cellulose as the substantive portion with a qualifying prefix. To specially distinguish the characteristic constituent of these compounds, that to which we have applied the neutral term non-cellulose, we employ the root of the prefix with the termination *in*, thus *pectin, lignin*.

In conformity with this plan it may be expedient to introduce such terms as subercellulose, cato-cellulose, suberin, cutin, and many others: but this should be left to be determined by the progress of investigation. The special classification and nomenclature proposed by Frémy has been already discussed, C. F. C.

**CERASIN**, the meta-acid (v. ARABIC ACID) existing in cherry-tree and plum-tree gums, and in the gums of other trees of the same family. Gum arabic yields cerasin when heated to  $150^\circ$  (Gélis, C. R. 44, 144). Cherry-tree gum is said to contain 52 p.c. arabin, 34.9 cerasin, 12 water, and 1 ash. Treated with nitric acid cerasin yield 15.5 p.c. mucic acid. C.O.S.

#### CERATIN v. PROTEINS.

**CERATOPHYLLIN**.<sup>20</sup> [147°]. Extracted by lime-water from the lichen *Parmelia ceratophylla* (Hesse, A. 119, 365). Thin prisms, sl. sol. cold, v. sol. hot, water; v. sol. alcohol, ether, and aqueous alkalis.  $Fe_2Cl_6$  colours its alcoholic solution purple. Bleaching-powder gives a red colour.

**CERPERIN**. A poisonous, crystalline glucoside occurring in *Cerbera Odollam* (Oudemans, J. pr. 99, 407; de Vrij, R. T. C. 3, 167).

**CEREBRIN** C.69-08, H.11-47, N.2-13, O.17-32 (Pareus). From these numbers the formulae  $C_{69}H_{108}N_2O_{13}$ ;  $C_{69}H_{134}N_2O_{11}$ ; or  $C_{69}H_{100}N_2O_{15}$  may be calculated). The body called *Phrenosin* by Thudichum (J. pr. [2] 25, 19) is probably the same body in an impure state. The name cerebrin was used first by Kühn (1828) and applied to a mixture of cholesterol and lecithin. It was used by Lassaigne (1830) to denote the entire substance that can be extracted from brain by alcohol. It was employed by Gobley (1850) to denote so-called 'protagon,' and by Müller to denote the nitrogenous substance free from phosphorus that can be extracted from the brain by alcohol, to which he gave the formula  $C_{17}H_{33}NO_3$ .

*References*.—Férrery, A. Ch. 16, 232; Frémy, J. Ph. 27, 453; Liebreich, A. 134, 29; Gobley, J. Ph. [4] 19, 346; W. Müller, A. 103, 131; 105, 361.

*Preparation*.—Ox-brain is freed from membranes, washed with water, squeezed and heated with baryta to boiling. The clear liquid is poured off and the coagulated residue washed with nearly boiling water, dried and extracted with alcohol. The first extract deposits very

little on cooling, but cerebrin mixed with cholesterol separates from the subsequent extracts. The cholesterol is removed by solution in ether. So prepared, cerebrin is free from phosphorus but contains inorganic matter. 250 grms. were got from 90 brains. It is redissolved in alcohol at 60° which leaves a barium salt undissolved. The barium that goes into solution is removed by a current of  $\text{CO}_2$ . The cerebrin is purified by frequent recrystallisations from alcohol. The earlier mother-liquors deposit on standing a gelatinous pp. By recrystallisation from alcohol this pp. may be separated into cerebrin (spherical crystals), homocerebrin (needles), and encephalin (R. Parcus, *J. pr.* 132, 310).

**Properties.**—Separates as a white crystalline powder composed of transparent globules from a boiling alcoholic solution. Soluble in acetone, chloroform, benzene, and glacial acetic acid. Insoluble in ether. Separates from acetone partly as globules, partly as matted threads. Cerebrin dissolves in conc.  $\text{H}_2\text{SO}_4$ . On standing exposed to the air, the liquid becomes covered with a purple skin, which afterwards turns green. Cerebrin does not combine with acids, bases, or salts. It is not affected by boiling for a short time with baryta. It is but slightly decomposed by boiling alcoholic potash. Cerebrin swells up but slightly in boiling water. It is very slightly hygroscopic, absorbing 2 p.c. of water from the air. It is decomposed by boiling for a long time with baryta. Boiled for some hours with dilute  $\text{HCl}$  it forms a solution that can reduce Fehling's solution.

**Homocerebrin** C. 70.1 p.c.; H. 11.6; N. 2.2; O. 16.1. The yield is  $\frac{1}{2}$  that of the cerebrin. Soluble in the same liquids as cerebrin; soluble also in boiling ether. Swells up in hot water, but does not form a paste. It is not decomposed by boiling water. Treated with hot  $\text{HCl}$ , it forms a solution that reduces Fehling's solution. Boiled for a long time with baryta, it is decomposed. It is not hygroscopic. Its solutions are neutral. It does not combine with acids, bases, or salts. It separates from alcoholic solutions in very fine needles. After separation from alcohol and drying, it is not a white powder (like cerebrin) but a waxy mass. It is more soluble in absolute alcohol than cerebrin.

**Encephalin.** C. 68.4; H. 11.6; N. 3.1; O. 16.9. Resembles homocerebrin rather than cerebrin. It separates from solutions in flexible plates. From acetone it separates in granular masses. It swells up with hot water forming a complete paste. Boiled with  $\text{HCl}$ , it forms a solution that can reduce Fehling's solution.

**CERIC ACID.** C. 64.2 p.c.; H. 8.8 p.c.; O. 27.0 p.c. Obtained by the action of  $\text{HNO}_3$  on cerin, or according to Kügler on phellonic acid  $\text{C}_{22}\text{H}_{22}\text{O}_3$  [96°]. Phellonic acid is obtained, together with glycerin and stearic acid, by the action of alcoholic  $\text{KHO}$  on cork that has previously been exhausted by chloroform and alcohol (Döpping, *A.* 45, 289).

**CERIN**  $\text{C}_{20}\text{H}_{20}\text{O}$  (?). [250°]. A substance that may be extracted by chloroform from cork, the bark of *Quercus Suber*, in which it occurs to the extent of 2 p.c. (Kügler, *Ar. Ph.* [3] 22, 217; cf. Chevreul, *A. Ch.* 96, 170; Döpping; *A.* 45, 289). Needles, insol. water, sol. other solvents. According to Siewert (*Z.* 12<sup>18</sup>, 383) an alcoholic

extract of cork contains phellyl alcohol  $\text{C}_{20}\text{H}_{20}\text{O}$  [100°], a neutral, crystalline substance, sl. sol. alcohol.

**CERIUM.** Ce. At. w. 139.9. Mol. w. unknown as element has not been gasified. S.G. (abt. 18°) 6.63 to 6.73 (Hillebrand & Norton, *P.* 156, 472). M.P. considerably above that of Sb (150°) but below that of Ag (950°) (H. & N.), 841. (0°-100°) 0.4479 (*M.*, *P.* 158, 7). S.V.S. 21.1. Chief lines in emission-spectrum 5352.2, 7273.2, 4628.2, 4572.6, 4562.1, 4296, 4289 (Thalén). In 1803 Klaproth, and independently Berzelius and Hisinger, separated a new earth from a Swedish mineral and called it *Ceria* (from the then recently discovered planet *Ceres*); in 1839-41 Mosander (*P.* 11, 406) proved that ceria was a mixture of at least three metallic oxides, oxides viz. of Ce, La, and Di. The metal cerium was first obtained by Mosander in 1826, it was more fully examined by Wöhler, Bunsen, and other chemists.

**Occurrence.**—In many Swedish minerals, more especially in *cerite* a silicate of Ce (abt. 56 p.c.  $\text{Ce}_2\text{O}_3$ ); occurs as silicate, phosphate, carbonate, fluoride, &c., also in many *apatites*; generally accompanied by La, Di, Fe, Al, &c. It has been recently found that clay used for brickmaking at Hanistadt (near Seeligenstadt in the neighbourhood of Frankfurt) contains from 8 to 12 p.c. of  $\text{Ce}_2\text{O}_3$  (Strohecker, *J. pr.* [2] 33, 133 a. 260).

**Preparation.**—*Cerite* is heated to redness, powdered, mixed with considerable excess of conc.  $\text{H}_2\text{SO}_4$ , and the mixture is gradually heated to incipient redness in a Hessian crucible; after cooling, the mass is powdered and then added, little by little, to ice-cold water, whereby sulphates of Ce, La, and Di are dissolved; the treatment with  $\text{H}_2\text{SO}_4$ , &c. is repeated with the portion insoluble in cold water; the aqueous solution is heated to boiling, whereby basic sulphates are pptd.; solution in ice-cold water and ppn. by heating to boiling are repeated several times (Marignac; Bunsen; Wöhler). The solution in cold water is pptd. by addition of oxalic acid solution; the oxalates are washed with water, dried, and heated in a Pt dish until completely converted into oxides. The mixed oxides (of Ce, La, and Di) may now be treated in many different ways. The following method was used by Fraunher (*C. J.* 47, 841) in order to prepare pure  $\text{Ce}_2\text{SO}_4$  for atomic weight determinations; it is based upon the formation of basic ceric nitrate insoluble in water. The mixed oxides were dissolved in moderately conc.  $\text{HNO}_3$ , excess of acid was removed by evaporation, and the syrup-like liquid was poured into much pure boiling water; the ppt. basic ceric nitrate was washed (on a funnel connected with a pump) with boiling water containing a little nitric acid. The nitrate was dissolved in  $\text{HNO}_3$ , excess of acid was removed by evaporation, the liquid was poured into boiling water, &c., as already described. This treatment was repeated 10 or 11 times. From the pure basic ceric nitrate thus obtained other Ce compounds may be prepared. Brauner prepared  $\text{Ce}_2\text{SO}_4$  by dissolving the basic nitrate in dilute  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_4$ , evaporating to dryness in a Pt dish, and heating with due precaution, dissolving in a little ice-cold water, ppg. by absolute alcohol, washing

with abs. alcohol, dissolving in ice-cold water, ppg. by alcohol, dissolving again, heating to 100° and stirring with a glass rod;  $\text{Ce}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$  was thus obtained; it was dehydrated by heating for some weeks at 440° in molten sulphur; at full redness the sulphate gives off  $\text{SO}_2$  and  $\text{SO}_3$ , and leaves pure  $\text{CeO}_2$ .

Robinson (*Pr.* 37, 150) prepared pure  $\text{Ce}_2\text{Cl}_6$ . The mixed oxides from cerite were dissolved in  $\text{HNO}_3$  aq. (*v. supra*), and the liquid, after concentration to a syrup, was poured into boiling dilute  $\text{H}_2\text{SO}_4$  aq.; the basic sulphates were dissolved in  $\text{HNO}_3$  aq.; the Ce salt oxidised by boiling with  $\text{PbO}_2$  (Gibbs, *Ann. S.* [2] 37, 352), the liquid evaporated, and  $\text{Ce}_2$  and  $\text{Di}$  salts removed by treatment with  $\text{HNO}_3$  aq.; the pure basic ceric nitrate remaining was converted into chloride by treatment with  $\text{HCl}$  aq., from this  $\text{Ce}$  oxalate was obtained by ppg. with oxalic acid; the oxalate was heated in dry  $\text{HCl}$ , and pure  $\text{Ce}_2\text{Cl}_6$  was thus obtained (for details *v. original*). Robinson (*l.c.*) also recommends evaporating the nitric acid solution of the mixed nitrates to complete dryness, heating the brown mass to full redness until the residue is pale-yellow, and treating this with boiling dilute  $\text{HNO}_3$  aq.; the basic nitrate remains while nitrates of  $\text{Di}$  and  $\text{La}$  dissolve.

Other methods for preparing more or less pure  $\text{Ce}$  salts are described by Bunsen, *P.* 155, 375; Czudnowicz, *J. pr.* 80, 16; Watts, *C. J.* 2, 147; Holtzmann, *J.* 1862, 136; Jolin, *Bl.* [2] 21, 533; Erk, *Z.* [2] 7, 100; Popp, *A.* 131, 361; Pattison a. Clark, *C. N.* 16, 259. Wöhler (*A.* 144, 251) prepared  $\text{Ce}$  by adding pieces of  $\text{Na}$  to a molten mixture of  $\text{Ce}_2\text{Cl}_6$ ,  $\text{KCl}$ , and  $\text{NH}_4\text{Cl}$ ; the product, however, was impure. Hillebrand a. Norton (*P.* 155, 633; 156, 466) by electrolysis  $\text{Ce}_2\text{Cl}_6$ , covered with  $\text{NH}_4\text{Cl}$ , using a thick iron wire as negative electrode (4 Bunsen's cells) obtained approximately pure cerium. (For details *v. original papers*.)

**Properties and Reactions.**—Steel-grey, very lustrous, very ductile, metal; malleable, unchanged in dry air, but in moist air is superficially oxidised; heated in air burns to oxide with production of heat and much light; burns in  $\text{Cl}$ ,  $\text{Br}$ ,  $\text{I}$  vapour,  $\text{S}$  vapour,  $\text{P}$  vapour, forming compounds with these elements; easily dissolved by  $\text{HCl}$  aq., dilute  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$  aq., no reaction with cold conc.  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$  aq.  $\text{Ce}$  slowly decomposes cold water, quickly decomposes hot water. As the V.D. of no  $\text{Ce}$  compound has yet been determined, the At. w. of the metal must be fixed by chemical considerations and by S.H. The value given to the At. w. for many years was abt. 92, and the formulæ of the oxides, and chloride, &c., were  $\text{CeO}$ ,  $\text{Ce}_2\text{O}_3$ ,  $\text{CeCl}_3$ , &c.;  $\text{Ce}$  was thus placed, along with  $\text{La}$  and  $\text{Di}$ , in the same class as  $\text{Al}$  and the earth metals. Considering the relations between the properties of compounds of  $\text{Ce}$ ,  $\text{La}$ ,  $\text{Di}$ , and of other elements, Mendeleeff (*A. Suppl.* 8, 186) thought that  $\text{Ce}$  ought to be classed with those elements which form well-marked oxides  $\text{MO}_2$ , i.e. with  $\text{Ti}$ ,  $\text{Zr}$ ,  $\text{Sn}$ , &c. If this were done the At. w. of  $\text{Ce}$  would become  $92 \times \frac{3}{2}$ . Further investigation has completely justified Mendeleeff's proposal;  $\text{Ce}$  is now classed with  $\text{C}$ ,  $\text{Si}$ ,  $\text{Ti}$ ,  $\text{Zr}$ ,  $\text{Sn}$ ,  $\text{Pb}$ , and  $\text{Th}$ ;  $\text{La}$  is placed with  $\text{Al}$  and the earth metals, and  $\text{Di}$  is classed with the elements

of Group V, whose characteristic highest oxide is  $\text{M}_2\text{O}_5$ .

The At. w. of cerium has been determined (1) by estimating  $\text{SO}_2$  in cerous sulphate (Beringer, *A.* 42, 134; Rammelsberg, *P.* 55, 65; Hermann, *J.* 30, 184; Marignac, *A. Ch.* [3] 27, 209; 38, 148). (2) by estimating  $\text{Cl}$  in cerous chloride (Beringer, *l.c.*; Robinson, *Pr.* 37, 150). (3) from combustions of cerous oxalate (Jogel, *A.* 105, 45; Rammelsberg, *P.* 108, 44). (4) by conversion of  $\text{Ce}_2\text{SO}_4$  into  $\text{CeO}_2$  by heat (Brauner, *C. J.* 47, 879). (5) by determining S.H. of approximately pure  $\text{Ce}$  (Hillebrand a. Norton, *P.* 156, 471). The most accurate determinations are those made by Robinson and Brauner, respectively: both lead to the number 139.90 ( $0 = 15.96$ ).

Cerium is distinctly metallic in its physical and chemical properties; it forms the oxides  $\text{Ce}_2\text{O}_3$  and  $\text{CeO}_2$  (and probably also  $\text{CeO}$ ), both of these are salt-forming in their reactions with acids, but the well-marked salts (cerous salts) are those corresponding to  $\text{CeO}_2$ , e.g.  $\text{Ce}_2\text{SO}_4$ , &c.; in this respect  $\text{Ce}$  differs from  $\text{La}$ ,  $\text{Zr}$ ,  $\text{Th}$ ,  $\text{Sn}$ , and  $\text{Pb}$ , the salts of which metals belong to the forms  $\text{MX}$  and  $\text{MX}_2$  ( $\text{X} = \text{SO}_4, \text{CO}_3, 2\text{NO}_3$ , &c.); and shows analogies with the elements of Group III. ( $\text{Al}$  &c.).  $\text{Ce}$  does, however, form a ceric sulphate  $\text{Ce}_2\text{SO}_4$ ; besides the oxide  $\text{CeO}_2$ , a fluoride  $\text{CeF}_3$ , analogous to  $\text{TiF}_3$ ,  $\text{ZrF}_4$ , &c., is known (*v. CARBON GROUP OF ELEMENTS; also TITANIUM GROUP OF ELEMENTS*.)

**Detection and Estimation.**— $\text{Ce}$  salts are generally soluble in water: all salts pp. white hydrated  $\text{Ce}_2\text{O}_3$ ;  $\text{NaCeO}_4$  pps. yellow hydrated  $\text{CeO}_2$  which dissolves in  $\text{HCl}$  aq. in presence of alcohol to form a colourless liquid; solutions of  $\text{Ce}$  salts are ppg. by oxalic acid, the ppg. oxalate is white and insoluble in  $\text{NH}_3$  salts; saturated  $\text{K}_2\text{SO}_4$  aq. pps. a white crystalline double sulphate, scarcely soluble in cold water, decomposed and dissolved by hot water containing a little  $\text{HCl}$ ;  $\text{Ce}$  salts boiled with  $\text{PbO}_2$  and a little  $\text{HNO}_3$  aq. give a yellow solution. When a slightly acid solution of a  $\text{Ce}$  salt is mixed with ammonium acetate, a little  $\text{H}_2\text{O}_2$  aq. is added, and the whole is warmed, a yellowish pp. is formed (Hartley, *C. J.* 41, 202); if this pp. is moistened with  $\text{NH}_3$  aq., again treated with  $\text{H}_2\text{O}_2$  aq., and warmed, an orange solid (?  $\text{CeO}_3$ ) is produced (de Boisbaudran, *C. R.* 100, 605).  $\text{Ce}$  can be separated from  $\text{La}$  and  $\text{Di}$  only by very prolonged treatment, *v. Preparation*.  $\text{Ce}$  is usually estimated as  $\text{CeO}_2$ , but it is very difficult to obtain this oxide pure. For methods of separation and estimation a manual of analysis must be consulted.

**Cerium, carbide of.** Said to be obtained as a dense black powder, insoluble in hot conc. acids, by heating cerous formate or oxalate in a stream of  $\text{H}$ , and treating with  $\text{HCl}$  aq. to dissolve out any oxide formed. Analyses agree approximately with composition  $\text{CeC}_2$  (Delafontaine, *J.* 1865, 177).

**Cerium, haloid and oxyhaloid compounds of.** Cerium forms cerous haloid compounds,  $\text{Ce}_2\text{X}_4$ , or  $\text{CeX}_3$ , corresponding to the oxide  $\text{Ce}_2\text{O}_3$ ; and also a ceric fluoride  $\text{CeF}_4$ ; the molecular weight of none of these compounds has been determined.

**CEROUS BROMIDE.**  $\text{CeBr}_3$  or  $\text{CeBr}_2$ . Known as the hydrate  $\text{CeBr}_3 \cdot 2\text{H}_2\text{O}$ . Obtained by dissolving cerous oxide,  $\text{Ce}_2\text{O}_3$ , in  $\text{HBrAq}$  and evaporating. Deliquescent needles; unchanged by heating out of contact with air; heated in air, partially decomposed with loss of Br. Forms double salt  $\text{CeBr}_3 \cdot \text{AuBr}_3 \cdot 8\text{H}_2\text{O}$  (Jolin, *Bl.* [2] 21, 323).

**CEROUS CHLORIDE.**  $\text{CeCl}_3$  or  $\text{CeCl}_2$ . Obtained by heating  $\text{Ce}$  in  $\text{Cl}_2$  or by dissolving  $\text{Ce}_2\text{O}_3$  in  $\text{HClAq}$ , adding  $\text{NH}_4\text{Cl}$ , evaporating to dryness, and driving off  $\text{NH}_4\text{Cl}$  by heating; or by passing a mixture of dry  $\text{CO}$  and  $\text{Cl}$  over hot  $\text{Ce}_2\text{O}_3$  (Didier, *C. R.* 101, 882). Pure  $\text{CeCl}_3$  was prepared by Robinson (*Pr.* 37, 150) by heating pure  $\text{Ce}_2(\text{C}_2\text{O}_4)_3$  in pure dry  $\text{HCl}$  gas to  $120^\circ\text{--}130^\circ$  for some time, then to  $200^\circ$ , and then to low redness; the small quantity of  $\text{C}$  separated was removed by heating at low redness in mixed  $\text{CO}_2$  and  $\text{HCl}$ ; finally the temperature was raised to a full red heat and the  $\text{CO}_2$  stream was stopped. The chloride was allowed to cool in  $\text{HCl}$  gas, transferred to a small flask, and kept *in vacuo*, over  $\text{H}_2\text{SO}_4$  and surrounded by  $\text{CaO}$ , until all  $\text{HCl}$  was removed. S.G.  $\frac{1.55}{1.53}$  (Robinson, *l.c.*). A white, deliquescent solid; easily soluble in water with production of heat; decomposed by  $\text{O}$  or  $\text{H}_2\text{O}$  steam, to  $\text{Ce}_2\text{O}_3$  (Didier). A hydrate,  $\text{CeCl}_3 \cdot 7\text{H}_2\text{O}$ , is said to be formed by digesting  $\text{Ce}_2\text{O}_3$  in  $\text{HClAq}$  and evaporating. Various double salts are described; e.g.

$\text{CeCl}_3 \cdot 4\text{H}_2\text{Cl}_2 \cdot 10\text{H}_2\text{O}$ ,  $\text{CeCl}_3 \cdot \text{PtCl}_4 \cdot 13\text{H}_2\text{O}$ ,  $\text{CeCl}_3 \cdot \text{AuCl}_3 \cdot 13\text{H}_2\text{O}$  (Jolin, *l.c.*).

**CEROUS CYANIDE** (and double cyanides) *v.* **CYANIDES.**

**CEROUS FLUORIDE.**  $\text{CeF}_3$  obtained as a gelatinous pp. ( $2\text{CeF}_3 \cdot \text{H}_2\text{O}$ ) by adding  $\text{NaFAq}$  to  $\text{CeCl}_3$  in  $\text{HClAq}$  (Jolin).

**CERIC FLUORIDE.**  $\text{CeF}_4 \cdot \text{H}_2\text{O}$ . An amorphous brown powder, insoluble in water, obtained by treating  $\text{CeO}_2 \cdot 6\text{H}_2\text{O}$  with  $\text{HFAq}$ , washing, and drying at  $100^\circ$ . Decomposed by heat with loss of  $\text{H}_2\text{O}$  and  $\text{HF}$  and formation of  $\text{CeF}_3$ ; heated strongly in contact with moist air  $\text{CeO}_2$  and  $\text{HF}$  are formed. Combines with  $\text{KF}$  (by treatment with  $\text{KF} \cdot \text{H}_2\text{O}$ ) to form  $2\text{CeF}_3 \cdot 3\text{KF} \cdot 2\text{H}_2\text{O}$  (Brauner, *C. J.* 41, 69).

**CEROUS IODIDE.**  $\text{CeI}_3$  or  $\text{CeI}_2$ . Obtained as the hydrate  $\text{CeI}_3 \cdot 9\text{H}_2\text{O}$ , in colourless crystals, by dissolving  $\text{Ce}_2\text{O}_3$  in  $\text{HIAq}$ , evaporating in a current of  $\text{H}_2\text{S}$ , and placing *in vacuo* over  $\text{H}_2\text{SO}_4$ ; soluble in water and alcohol, very quickly decomposes in air (Lang, *J. pr.* 82, 134).

**CERIUM OXYCHLORIDES.** The compound  $\text{Ce}_2\text{O}_3\text{Cl}_2$  (=  $\text{Ce}_2\text{O}_3 \cdot 2\text{CeCl}_2$ ) is said to be formed when  $\text{CeCl}_3$  is heated with  $\text{Na}$  (in preparation of  $\text{Ce}$ ) and the mass is treated with water. Dark purple, lustrous, powder; insoluble in water (Wöhler, *Abh.* 144, 254). The same oxychloride is said to be obtained, as iridescent scales, by passing a mixture of steam and  $\text{N}$  over a fused mixture of  $\text{CeCl}_2$  and  $\text{NaCl}$ ; easily soluble in dilute acids; heated in air gives  $\text{Ce}_2\text{O}_3$  and  $\text{HCl}$  (Didier, *C. R.* 101, 882).

**Cerium, hydroxides of, v. CERIUM, OXIDES OF.**

**Cerium, oxides and hydrated oxides of.** The best studied oxides are cerous oxide  $\text{Ce}_2\text{O}_3$ , and ceric oxide  $\text{CeO}_2$ ; a peroxide  $\text{CeO}_4$  also probably exists. Other oxides, e.g.  $\text{Ce}_2\text{O}_5$  and  $\text{Ce}_3\text{O}_4$ ,

have been described, but their existence is very doubtful.

**CEROUS OXIDE.**  $\text{Ce}_2\text{O}_3$ . (*Cerium sesquioxide.*) Mol. w. unknown. The white, bulky pp. obtained by adding  $\text{KOH Aq}$  to a solution of a cerous salt is hydrated cerous oxide; as the pp. at once begins to take up  $\text{O}$  and  $\text{CO}_2$  from the air the hydrate has not yet been obtained pure. The oxide  $\text{Ce}_2\text{O}_3$  is prepared by heating cerous oxalate in a stream of pure  $\text{H}_2$ . The oxalate is prepared from the basic nitrate (*v. CERIUM, Preparation*) by dissolving in a little  $\text{HNO}_3\text{Aq}$  and ppt. by oxalic acid (Popp, *A.* 131, 361; Rammelsberg, *B.* 6, 86).

**Properties and Reaction.** A grey solid; unchanged by heating in  $\text{H}_2$ . Dissolves in many acids to form cerous salts of the form  $\text{CeX}_3$ ,  $\text{X} = \text{SO}_4, \text{CO}_3, 2\text{NO}_3, 2\text{ClO}_4$ , &c.

**CERIC OXIDE.**  $\text{CeO}_2$ . (*Cerium dioxide.*) The pale yellow pp. obtained by suspending  $\text{Ce}_2\text{O}_3 \cdot \text{H}_2\text{O}$  in  $\text{KOH Aq}$  and passing in  $\text{Cl}$  is hydrated ceric oxide ( $2\text{CeO}_2 \cdot 3\text{H}_2\text{O}$ ; Rammelsberg, *l.c.* 108, 40).

**Formation.**—1. By washing the hydrate with water containing a little acetic acid until  $\text{KOH}$  is removed, drying and heating. —2. By heating cerous sulphate  $\text{Ce}_2(\text{SO}_4)_3$  to full redness in air. 3. By heating  $\text{CeF}_3$  in air (Brauner).

**Preparation.**—Cerous oxalate is prepared from the basic nitrate from cerite (*v. CERIUM, Preparation*); it is heated to redness in a Pt dish with free access of air. Nordenskiöld (*P.* 114, 616) obtained colourless, transparent, sesquial crystals of  $\text{Ce}_2\text{O}_3$  by heating  $\text{Ce}_2\text{O}_3$  for 24 hours with a little borax in a porcelain oven, and treating the mass with  $\text{HClAq}$ ; S.G. at  $15^\circ = 6.94$ .

**Properties and Reactions.**—Very pale yellow solid (Wolp, Fraumer, Robinson (*C. N.* 54), Crookes, *Pr.* 38, 414). S.G. 6.74 (Nilson a. Petersson, *P.* 13, 1159). S.V.S. 25.45. S.H. 0.877 (N. a. P., *Pr.* 31, 46). Dissolves in conc.  $\text{H}_2\text{SO}_4\text{Aq}$  with production of much heat, and evolution of some  $\text{O}$ ; on crystallising, the salt  $\text{Ce}_2(\text{SO}_4)_3 \cdot \text{Ce}(\text{SO}_4)_2 \cdot 24\text{H}_2\text{O}$  separates (Mendelejeff, *A.* 168, 45); from the mother-liquor of this salt ceric sulphate  $\text{Ce}_2(\text{SO}_4)_3 \cdot 4\text{H}_2\text{O}$  is obtained. This reaction shows that part of the  $\text{CeO}_2$  is reduced by the  $\text{H}_2\text{SO}_4$  to  $\text{Ce}_2\text{O}_3$ , and part reacts with the acid to form  $\text{Ce}_2(\text{SO}_4)_3$ . Dissolves in  $\text{HNO}_3\text{Aq}$ ; on adding  $\text{NH}_4\text{NO}_3$  and crystallising *in vacuo* the double salt  $2\text{Ce}(\text{NO}_3)_3 \cdot 4\text{NH}_4\text{NO}_3 \cdot 3\text{H}_2\text{O}$  is obtained. Scarcely soluble in  $\text{HClAq}$ ; but dissolves in this acid, and also in other dilute acids, in presence of reducing bodies, e.g. filter paper, alcohol,  $\text{SO}_2\text{Aq}$ , &c.

**CERIUM TEROXIDE.**  $\text{CeO}_4$ . (*Cerium peroxide.*) Said to be obtained as a reddish pp. by adding a slight excess of  $\text{NH}_4\text{NO}_3$  to  $\text{Ce}_2(\text{SO}_4)_3\text{Aq}$ , and digesting with hydrogen peroxide (de Boisbaudran, *C. R.* 100, 605; Cleve, *Bl.* [2] 43, 53).

**OTHER OXIDES OF CERIUM** are described by Popp (*A.* 131, 361); Lermann (*J. pr.* 30, 184; 82, 385; 92, 113); the formulae  $\text{Ce}_2\text{O}_5$  and  $\text{Ce}_3\text{O}_4$  are assigned to these oxides, respectively; but experiments made by Rammelsberg (*P.* 108, 40) and others tend to show that the only oxides which have been isolated are  $\text{Ce}_2\text{O}_3$ ,  $\text{CeO}_2$ , and  $\text{CeO}_4$ .

**Cerium, oxychlorides of, v. under CERIUM, HALOID AND OXYHALOID COMPOUNDS OF.**

**Cerium, salts of.**—Salts obtained by replacing H of acids by Ce. Two series of salts are known, cerous salts represented by  $\text{Ce}_2\text{SO}_4$ , and ceric salts represented by  $\text{Ce}_2\text{SO}_4$ . The cerous salts correspond to the oxide  $\text{Ce}_2\text{O}_3$ , the general form of these salts is  $\text{Ce}_x\text{X}_y$ , where  $\text{X} = \text{SO}_4, \text{CO}_3, 2\text{NO}_3, 2\text{ClO}_4$ , &c.; the ceric salts correspond to the oxide  $\text{CeO}_2$ , their general form is  $\text{Ce}_x\text{X}_y$ , where  $\text{X} = \text{SO}_4$ , &c. The cerous salts are considerably more stable than the ceric salts; the latter are readily reduced to the former; but few ceric salts have been obtained, the principal salt is  $\text{Ce}_2\text{SO}_4$ ; several double salts are known of the form  $\text{Ce}_2\text{SO}_4 \cdot x\text{M}_2\text{SO}_4$ , and  $\text{Ce}(\text{NO}_3)_4 \cdot x\text{MNO}_3$ , when M is an alkali metal. Many double cerous salts are known. A few basic salts are also known. Some salts have been isolated which appear to belong to the mixed form  $x\text{Ce}_2\text{X}_y \cdot y\text{CeX}_z$ ; and one of the so-called basic nitrates is probably  $x\text{Ce}_2\text{ONO}_2 \cdot y\text{CeO}_2$ . For descriptions of the individual salts v. the articles on the various groups of salts, carbonates, sulphates, &c.; the chief salts are the bromate, carbonates, iodate, nitrates, oxalate, perchlorate, phosphates, selenate, sulphates, tungstate.

**Cerium silicide.** Described by Ullrich (Z. [2] 2, 60) as a brown powder; obtained by passing an electric current from 8 Bunsen-cells through a fused mixture of  $\text{Kf}$  and  $\text{Ce}_2\text{F}_6$  in a porcelain crucible, and treating with water the brownish mass formed at the negative pole. The Si was derived from the crucible which was strongly attacked. Analysis gave numbers nearly agreeing with the formula  $\text{Ce}_2\text{Si}$ .

**Cerium, sulphides of.** Only one sulphide is known, cerous sulphide,  $\text{Ce}_2\text{S}_3$ . It is best obtained by passing dry  $\text{H}_2\text{S}$  over  $\text{CeO}_2$  heated to full redness in a porcelain tube. S.G. 5.1. Vermillion to black according to the temperature at which prepared. May also be obtained in red translucent crystals by passing dry  $\text{H}_2\text{S}$  over a fused mixture of dry  $\text{NaCl}$  and dry  $\text{Ce}_2\text{Cl}_6$ , and then washing with water. Unchanged in ordinary air; but burnt to  $\text{SO}_2$  and  $\text{CeO}_2$  below a red heat in air. Dissolves easily in dilute acids with production of  $\text{H}_2\text{S}$ ; very slowly decomposed by warm water (Didier, C. R. 100, 1461; v. also Lange, J. pr. 82, 129; and Mosander, P. 11, 406).

**Cerium, sulphocyanide of;** v. SULPHOCYANIDES, under CYANIDES. M. M. P. M.

**CEROPIC ACID**  $\text{C}_{20}\text{H}_{30}\text{O}_2$  (?) In the leaves of the Scotch fir (*Pinus sylvestris*), from which it may be extracted by dilute alcohol. Minute needles.— $\text{BaA}''$  aq (Kawaler, d. 88, 360).

**CEROSIN**  $\text{C}_{22}\text{H}_{34}\text{O}$  [82°]. A waxy substance found on the stem of the sugar-cane. Nacreous laminae (from alcohol). Heating with potash-lime oxidises it to cerous acid  $\text{C}_{22}\text{H}_{30}\text{O}_3$  (?) [93°], which may be crystallised from petroleum (Avequin, A. Ch. 75, 218; Dumas, A. Ch. 75, 222; Lewy, A. Ch. [3] 13, 438).

**CEROTENE**  $\text{C}_{27}\text{H}_{44}$  [58°] A product of the distillation of Chinese wax (Brodie, P. M. [3] 83, 378; A. 67, 210). Resembles paraffin. Chlorine forms  $\text{C}_{27}\text{H}_{37}\text{Cl}_{10}$ ,  $\text{C}_{27}\text{H}_{32}\text{Cl}_{21}$ , and  $\text{C}_{27}\text{H}_{24}\text{Cl}_{22}$ . A similar body [66°] occurs in hay; it is perhaps  $\text{C}_{26}\text{H}_{42}$  (König & Kiesoff, B. 6, 500).

**CEROTIC ACID**  $\text{C}_{27}\text{H}_{44}\text{O}_2$  or  $\text{C}_{26}\text{H}_{42}\text{O}_2$ . [78°]. Occurrence.—1. As ceryl cerotate in Chinese

wax; whence it is obtained by distillation, or, better, by treatment with alcoholic KOH.—2. In the free state in bee's wax (John, *Chemische Schriften*, 4, 38; Boudet & Boissot, J. Ph. 13, 88; Hülting, A. 2, 267; Hess, A. 27, 3; Gerhardt, Rev. scient. 19, 5; Lewy, A. Ch. [3] 13, 438; Brodie, A. 67, 180; Zatzek, M. 3, 677).

**Formation.**—By oxidation of paraffin with dilute  $\text{HNO}_3$  or with chromic mixture (Gill & Meusel, C. J. 21, 466). Also by heating ceryl alcohol with soda-lime (Schwälb, A. 235, 141).

**Preparation.**—The alcoholic extract from bee's wax is recrystallised till it melts at 70°. This is dissolved in alcohol and the lead salt thrown down by alcoholic lead or cuprio acetate.

**Salts.**— $\text{NaA}'$ .— $\text{CuA}'$ , at 100°.— $\text{PbA}'$ , [113°].— $\text{KA}'$ .— $\text{MgA}'$ ? [140°–145°].— $\text{AgA}'$ .

**Methyl ether MeA'**. [60°] (Natzger, A. 224, 233).

**Ethyl ether EtA'**. [60°]. Fatty plates (from alcohol). Soluble in ether. May be distilled *in vacuo*. On distillation it gives off  $\text{C}_2\text{H}_4$  and  $\text{CO}_2$  and the distillate contains cerotic acid and a paraffin [14°] ( $\text{C}_{26}\text{H}_{54}$ , or  $\text{C}_{27}\text{H}_{56}$ ) while in the retort there remains a ketone [92°] which is  $(\text{C}_{26}\text{H}_{52})\text{CO}$  or  $(\text{C}_{26}\text{H}_{54})\text{CO}$ .

**Ceryl ether**  $\text{C}_{27}\text{H}_{52}\text{O} \cdot \text{C}_{27}\text{H}_{52}\text{O}$ . [82°] Occurs almost pure as Chinese wax (Brodie) Occurs also in opium-wax (Hesse, B. 3, 638) and in yolk, the sweat of sheep (Buisson, Bl. 2, 42, 201).

An acid [79°] isomeric or identical with cerotic acid is the chief acid present in the product of saponification of carnauba wax. From alcohol it separates as a jelly, but from other solvents (ether, benzene, light petroleum) as a crystalline powder (Stürcke, A. 223, 283; cf. Bérard, Z. [2] 6, 465).

**Salt.**— $\text{PbA}'$ , [110°]. Sol. boiling glacial acetic acid and toluene. Insol. boiling alcohol or ether.

**CEROTONE**  $\text{C}_{27}\text{H}_{50}\text{O}$  i.e.  $(\text{C}_{27}\text{H}_{50})\text{CO}$  (?) [62°] Formed by distilling lead cerotate (Brückner, J. pr. 57, 17). Plates (from ether).

**Cerotone**  $(\text{C}_{26}\text{H}_{52})\text{CO}$  (?) [92°]. Formed by distilling cerotic acid or its ethyl ether (Natzger, A. 224, 237). Plates (from acetone).

**CERYL ALCOHOL**  $\text{C}_{27}\text{H}_{56}\text{O}$  or  $\text{C}_{26}\text{H}_{54}\text{O}$  [79°].

**Occurrence.**—Chinese-wax consists almost entirely of ceryl cerotate (Brodie, A. 67, 180; Schwälb, A. 235, 141). Ceryl cerotate also occurs in the sweat on the wool of sheep. The wax outside ripe heads of the opium poppy contains ceryl cerotate and ceryl palmitate, [79°] (Hesse, B. 3, 637).

**Preparation.**—Chinese-wax is saponified with alcoholic potash, the product mixed with baric chloride solution and the ceryl alcohol separated from baric cerotate by solution in alcohol.

**Reactions.**—Is oxidised to cerotic acid  $\text{C}_{27}\text{H}_{50}\text{O}_2$  by heating with soda-lime.

**Iso-ceryl alcohol**  $\text{C}_{27}\text{H}_{56}\text{O}$ . [62°]. The portion of the wax of *Ficus gummiflua* which is insoluble in cold ether (Kessel, B. 11, 2113).

**Acetyl derivative**  $\text{C}_{27}\text{H}_{50}\text{OAc}$ . [57°]. **CESPTINE**  $\text{C}_{27}\text{H}_{52}\text{N}$  (?). [95°]. Occurs in coal tar, and in the product of the distillation of peat (Church & Owen, P. M. [4] 20, 110; Fritzsche, J. 1868, 402). Liquid, miscible with water. Combines with EtH. Its platinochloride is de-

composed by boiling water (De Coninck, *Bt.* [2], 43, 181). Goldschmidt a. Constam (*B. 16*, 2978) suggest that it is wet pyridine.

#### CETANE v. HEXADECANE.

**CETENE**  $C_{16}H_{32}$  i.e.  $CH_3(CH_2)_{14}CH_3$ . *Cetylene. Hexadecylene.* [49] (275°); (155°) at 15 mm. S.G.  $\frac{1}{4}$  7917;  $\frac{1}{16}$  7842. V.D. 8.0. Formed by distilling cetyl alcohol with  $P_2O_5$  (Dumas a. Péligot, *A. Ch.* [2] 62, 4; Smith, *A. Ch.* [3] 6, 40). Also by distilling cetyl palmitate or commercial spermaceti (cf. Krafft, *B.* 16, 3018). Oil; sol. alcohol and ether. According to Berthelot (*A. Ch.* [3] 51, 81) it forms unstable compounds with  $HBr$  and  $PCl_5$ . It forms a dibromide  $C_{16}H_{32}Br_2$  [14°] whence alcoholic KOH forms oily bromo-cetene (Chydenius, *A.* 143, 267).  $HClO$  forms chloro-cetyl alcohol  $C_{16}H_{31}Cl(OH)$  (c. 300°) (Carius, *A.* 126, 195).  $SO_3$  forms  $C_{16}H_{31}SO_3H$  [18°], insol. water.— $KA'$ : [106°]; *S.* 1 (Lasarenko, *B.* 7, 125).

An isomeride of cetene, [42°], [281°] is got by distilling azelaic acid with baryta (Schorlemmer, *A.* 136, 265).

**CETENE GLYCOL.** The *di-acetyl derivative*  $C_{16}H_{32}(OAc)_2$  is formed by the action of  $AgOAc$  on cetene dibromide. It cannot be distilled (Chydenius, *A.* 143, 270).

**CETENE OXIDE**  $C_{16}H_{32}O$  [below 30°], (below 300°). From chloro-cetyl alcohol (cf. Cetene) and aqueous KOH (Carius, *A.* 126, 202). Minute needles.

**CETIC ACID**  $C_{15}H_{31}O_2$  [55°]. The glyceryl derivative occurs in the oil expressed from the seeds of *Jatropha Curcas* (Bouis, *J.* 1851, 462). According to Heintz (*P.* 90, 137) a very small quantity of this acid is found in the products of saponification of spermaceti.

*Ethyl ether EtA'*. [21°] (*P.*).

**CETYLENE**  $C_{16}H_{14}$ . *Cetylene. Hexadecene. Hexadecylidene.* [20°]. (284°) (160°) at 15 mm. S.G.  $\frac{20}{4}$  = 804;  $\frac{30}{16}$  = 797. H.F. 113,000 (Berthelot). Large colourless tables. Formed by heating cetene, (hexadecylene) bromide (natural or synthetic) with alcoholic KOH (Krafft, *B.* 17, 1373; cf. Chydenius, *C. R.* 64, 180).

**CETRARIIC ACID**  $C_{16}H_{31}O_4$ . Contained, together with lichonostearic acid, in Iceland moss (*Cetraria islandica*) (Berzelius, *Schw. J.* 7, 317; *A. Ch.* 90, 277; Herberger, *A.* 21, 137; Knop a. Schnedermann, *A.* 55, 144). Hair-like needles (from alcohol), v. sl. sol. water, sl. sol. ether, v. sol. boiling alcohol. Tastes bitter. Decomposed before melting. Its solutions turn brown on boiling, especially in presence of alkali.  $FeCl_3$  gives a red pp. in neutral solutions.— $(NH_4)_2A''$ .— $PbA''$ .

**DICETYL**  $C_{32}H_{66}$ . *Dotriacontane.* [70°]. (above 300°). V.D. 15.8. Formed by treating an ethereal solution of cetyl iodide with sodium (Sorabji, *C. J.* 47, 37; cf. Lebedeff, *J. R.* 1881, [2] 299). Scales, v. sl. sol. ether, v. sol. boiling glacial  $H_2OAc$ .

**CETYL ACETATE**  $C_{16}H_{33}OAc$ . *n-Prim-hexadecyl acetate.* [19°] (Becker, *A.* 103, 220) [23°] (Krafft, *B.* 16, 1721). (278°) at 190 mm.; (200°) at 15 mm. (*K.*). S.G.  $\frac{15}{4}$  = 8640;  $\frac{25}{16}$  = 8612.  $MM.$  18.772 at 20.7° (Perkin, *C. J.* 45, 421). Needles; sl. sol. cold alcohol.

**CETYL-ACETIC ACID** is identical with **SEARIC ACID** (*q. v.*).

**Di-cetyl-acetic acid**  $C_{32}H_{64}O_4$  i.e.  $(C_{16}H_{31})_2CH_2CO_2H$ . [70°]. Formed by heating di-cetyl-malonic acid at 150° (Guthzeit, *A.* 206, 365). Crystalline scales, sl. sol. alcohol.— $AgA'$ : amorphous pp.

**CETYL ALCOHOL**  $C_{16}H_{33}O$ . *Æthyl. n-Prim-hexadecyl alcohol.* Mol. v. 212. [50°]. (844°); (130°) at 15 mm. S.G. (liquid)  $\frac{50}{4}$  = 8176;  $\frac{60}{4}$  = 8105;  $\frac{70}{16}$  = 7837. H.F. 112,000 (Berthelot).

*Occurrence.*—Spermaceti is cetyl palmitate  $(C_{16}H_{33})_2C_{18}H_{37}O_2$  (Chevreul, *Recherches sur les Corps gras*, p. 171; Dumas a. Péligot, *A. Ch.* [2] 62, 4; Dumas a. Stas, *A. Ch.* [2] 73, 124; Smith, *A. Ch.* [3] 6, 40; *A.* 42, 247; Heintz, *P.* 84, 232; 87, 553). In the sebaceous glands of geese and ducks (De Saenge, *H.* 3, 225).

*Formation.*—By the distillation of bario sebacate (Schorlemmer, *Pr.* 19, 22).

*Preparation.*—1. Spermaceti (10 pts.) is boiled with alcohol (5 pts.) and potash (2 pts.) until saponified. The product is poured into water and the cetyl alcohol crystallised from ether. The crude commercial cetyl alcohol contains in addition to hexadecyl alcohol also *n-p*-octadecyl alcohol and probably small quantities of other homologues (Krafft, *B.* 17, 1627).—2. The acetate is formed by reducing palmitic aldehyde (obtained by distilling barium palmitate with barium formate) with zinc-dust and acetic acid (Krafft, *B.* 16, 1721).

*Properties.*—Small crystalline plates (from alcohol). Gives palmitic acid on oxidation.

Sodium Cetylate  $C_{16}H_{33}NaO$ . [110°] (Fridau, *A.* 83, 1).

**Æthyl ether**  $C_{16}H_{33}OEt$ . [20°] (Becker, *A.* 102, 220).

**TRI-CETYL-AMINE**  $C_{48}H_{99}N$  i.e.  $(C_{16}H_{33})_3N$ . [39°]. From cetyl iodide and gaseous  $NH_3$  at 150° (Fridau, *A.* 83, 25). Needles. Its salts are insol. water, sol. alcohol and ether.— $B'HCl$ .— $(B'HCl)_2PCl_5$ : yellow pp.

**CETYL-ANILINE**  $C_{31}H_{41}N$  i.e.  $N(C_{16}H_{33})(C_{15}H_{11})$ . *n-Prim-cetyl-amine.* [42°]. From cetyl iodide and aniline at 100° (Fridau, *A.* 83, 29). Silvery scales (from alcohol). Has no action on litmus, and does not pp. metallic salts.  $B'H_2PtCl_6$ .

**Di-cetyl-aniline**  $N(C_{16}H_{33})(C_{16}H_{33})_2$ . From cetyl-aniline and cetyl iodide at 110° (*F.*). Crystalline.— $B'H_2PtCl_6$ .

**CETYL-BENZENE**  $C_{31}H_{40}$  ( $C_{16}H_{33}$ ). *Hexadecylbenzene.* [27°]. (230° at 15 mm.). Formed by the action of sodium upon a mixture of iodo-benzene and cetyl iodide (Krafft, *B.* 19, 2983).

**CETYL-BENZENE-SULPHONIC ACID**  $C_{16}H_{33}(C_{16}H_{33})SO_3H$ . *Hexadecyl-benzene-sulphonic acid.* Formed by sulphonating cetyl-benzene. The sodium salt  $A'Na$  is sparingly soluble (Krafft, *B.* 19, 2983).

**CETYL BENZOATE**  $C_{31}H_{40}O_2$ . [30°] (Becker, *A.* 102, 219). Crystalline scales.

**CETYL BORATE**  $C_{16}H_{33}BO_2$ . [58°] (Schiff, *A. Suppl.* 5, 198).

**CETYL BROMIDE**  $C_{16}H_{33}Br$ . [15°]. From cetyl alcohol,  $Br$ , and  $P$  (Fridau, *A.* 83, 15). Insol. water, v. sol. alcohol and ether.

**CETYL CHLORIDE**  $C_{16}H_{33}Cl$ . S.G. 12.841. From cetyl alcohol and  $PCl_5$ .  $OH$ , insol. alcohol, sol. ether. Boils above 280° with decomposition (Dumas a. Péligot, *A. Ch.* 69, 4; Tütt-scheff, *Rép. Chim. pure*, 2, 463).

### CHEMICAL AND PHYSICAL PROPERTIES OF BODIES, CONNEXIONS BETWEEN.

Certain properties are common to all kinds of matter, others are characteristic of this or that kind only. Thus, every material substance is acted on by the force of gravity in exactly the same manner, but only a few liquids rotate the plane of polarisation of a ray of light. Properties belonging to the second of these classes are subdivided into two groups, physical and chemical properties. Chemistry deals with those changes in the properties of material bodies which are accompanied by changes in the composition of the bodies. Physics deals with changes in the properties of bodies the composition of which remains the same. When the totality of properties by which a body is known remains unaltered throughout any process, that process is called physical; when the result of any process is a body or bodies with properties so different from the totality of those of the original that the original can no longer be said to exist, that process is called chemical. Physical and chemical processes are always closely connected in their occurrence; no chemical change takes place without some accompanying physical change, and it is probable that every physical change is to some extent accompanied by chemical change. Many physical properties are quantities which may be accurately measured; e.g. melting- and boiling-points, specific gravity, &c., &c. Change of composition of a body or system of bodies is very frequently accompanied by change in the value of one or more of these measurable quantities; in other words, the physical constants of a body are conditioned, among other circumstances, by changes in the variable, chemical composition. By the chemical composition of any homogeneous kind of matter is meant, in the first place, a statement of the elements, and of the mass of each element, in a given mass of that body: in this meaning of the term the chemical composition of a body, or system can be accurately stated, and definite relations can be determined between changes in the composition and changes in the values of such physical properties as melting- and boiling-points, specific rotatory power, specific refractive energy, and so forth. When the relations between the two groups of changes have been studied and generalised, it may become possible to infer the amount and character of a change of composition from measurements of the changes in the values of a few physical properties. It would be impossible to study the relations between every chemical change and the accompanying variations in the physical properties of the bodies forming the changing system; it is necessary to select typical cases, and to study these as accurately and minutely as possible. As a rule, one physical property is chosen for measurement; the composition of the system is allowed to begin with; the system is allowed, or caused, to pass into another definite state; and the variation in the value of the chosen property is determined.

But when it is found that several distinct kinds of matter exist, each homogeneous, each distinguished by definite properties, and each containing in a given mass the same masses of

the same elements, it becomes necessary to widen the meaning of the expression chemical composition. It becomes necessary to frame an hypothesis to account for the observed facts. The hypothesis generally adopted asserts that matter has a grained structure, that a mass of any kind of homogeneous matter is composed of a vast but not indefinite number of minute parts; and that the properties of the mass are conditioned by the properties of these parts. These minute portions of matter are called molecules. But the molecule is not necessarily itself without parts. The chemist asserts that every molecule is built up of a definite number of smaller parts—either of one or of several kinds of matter. These parts of molecules are called atoms. The atoms of elements are the ultimate forms of matter with which chemistry at present concerns itself. The hypothesis goes on to assert that the properties of a molecule, and hence the properties of any portion of homogeneous matter composed of molecules of this kind, are conditioned by the nature, the number, and the relative arrangement, of the atoms which together form the molecule. In other words, the hypothesis declares that the molecule is itself a structure. On this hypothesis, by the chemical composition of a body is meant a statement of the nature, number, and relative arrangement, of the atoms which form a molecule of the body. We know as yet almost nothing about the configuration of atoms in molecules; but chemistry has formed certain more or less clear hypotheses, and attempts are constantly being made to connect changes in the values of various physical properties with variations in the relative arrangement of atoms in molecules, as this arrangement is conceived by the hypotheses in question.

But the physical conception of the molecule is derived from the study of various gaseous phenomena: the physicist deals with the molecule as a whole; he pictures the molecules as performing certain vibrations, on the form, amplitude, and rate, of which the physical properties of bodies depend. The two conceptions, the chemical and the physical conception, of the molecule are therefore to a great extent mutually independent. In how far then, one may ask, can a development of the chemical conception be looked for by using physical methods of inquiry? Looking at recent researches, it seems probable that the chemical conception of the molecule must be very considerably modified, and must be brought more into harmony with the physical conception. The latter is itself to some extent being changed by the development of the theory of vortex atoms. But it must not be forgotten that the physical conception, in so far as it is a clear conception, has been developed almost wholly from the study of gaseous laws, more especially of the laws which express the relations of the volumes of gases to temperature and pressure; these relations are dependent on the states of combination of the parts of molecules, and are in no way affected by the nature or number of these parts. The chemical conception, on the other hand, must be made sufficiently elastic to cover the phenomena presented by gaseous,

liquid, and solid, compounds; and most of the chemical processes which occur among compounds, belonging to these classes, are conditioned both by the nature and number, and by the states of combination of the atoms which form the chemical molecules of the reacting bodies. The chemical conception of the molecule will probably be modified when we know more of those properties which, like the relation between the volumes of gases and the temperature and pressure of these gases, are to a great extent, if not altogether, independent of the nature and numbers of the constituent parts of molecules. The physical conception will probably be modified as we learn more of those properties which, like specific heat, are for the most part dependent on the nature and numbers of the constituent parts of molecules. (v. MOLECULAR STRUCTURE OF MATTER, THEORIES REGARDING).

Chemistry regards not only changes in the composition, but also changes in the properties, of bodies; she attempts to generalise not only the laws of composition, but also those of the mutual actions, of bodies. The study of the connexion between changes of composition and variations in physical properties of chemically reacting bodies will throw light on the nature of chemical change. When accurate measurements have been made of the quantities of heat which disappear or are produced in a series of typical chemical processes we shall be able to apply to these processes the knowledge of heat-energy which is generalised in the thermodynamical laws. Chemical change may then perhaps be shown to be a special instance of the working of these laws. The conditions of chemical change on the one hand, and of physical change on the other, must be studied, in order that the laws which express these conditions may be gained; the relations between these two groups of laws must then be ascertained; thus it may become possible to attain to clear mental images of natural phenomena as wholes which now present one aspect to the physicist and another to the chemist.

For accounts of the various physical methods employed in chemistry, and résumés of the more important results, v. PHYSICAL METHODS.

M. M. P. M.

**CHEMICAL CHANGE.** Chemical science is based upon the hypothesis that matter is constituted of extremely small particles or atoms, and that these atoms are capable of aggregating together by virtue of certain inherent properties or forces, their affinities, to form complex atomic structures or groupings.

The recognition of this distinctive force by the older chemists led them to propound various theories to account for its existence and explain the phenomena of chemical action (v. AFFINITY).

With the nature of this force we are not concerned here, but only with the phenomena that accompany its exhibition and the circumstances that modify its action.

By a chemical change, therefore, is meant any alteration either (1) of the character of a permutation in an atomic group, such for instance as is exhibited in the change of ammonium cyanate,  $\text{NH}_4\text{CNO}$ , into urea ( $\text{NH}_2$ ),  $\text{CO}$ , or (2) a permutation between two or more such groups,

as  $\text{AB} + \text{CD} = \text{AD} + \text{BC}$ , which groups may be of various degrees of complexity; or (3) the change may arise from a combination such as  $\text{AB} + \text{CD} = \text{ABCD}$ , or the converse of this, as is seen in the phenomena of dissociation.

The majority of chemical changes may be formulated as permutations between two sets of atomic groups; such as the action of bases on acids, the decomposition of one salt by another, or the combination between gaseous elements as  $\text{H}_2 + \text{Cl}_2 = 2\text{HCl}$ . Examples of chemical change according to case (3) are of less frequent occurrence than the last; such are the formation of double salts like the alums, the combination of certain gaseous molecules with oxides, &c., as  $\text{CaO} + \text{CO}_2 = \text{CaCO}_3$ , and  $\text{CO} + \text{Cl}_2 = \text{COCl}_2$ . The number of strikingly marked instances that could come under the head of permutations in an atomic group is very small, but such changes may be of frequent occurrence, producing alterations in physical and chemical properties too slight to be recognisable.

There are several bodies which are known to undergo remarkable and highly interesting physical, and consequently no doubt chemical, changes, when heated, but whether such changes come under class (1) or class (3) is undecided. Among such substances are phosphorus, paracyanogen, and cyanuric acid. In the case of phosphorus, the change from the yellow to the red modification, caused by heat or light, is probably due to an alteration in the state of aggregation of the atoms; that is to say, if the molecule of yellow phosphorus be  $\text{P}_4$ , that of the red modification is probably  $\text{P}_n$ ; for solid paracyanogen, which is converted by heat into gaseous cyanogen, and for cyanuric acid, the same may be true, with or without a re-arrangement among the constituent atoms of the molecules (v. ALLOTROPY and ISOMERISM).

The study of the phenomena attending a chemical change shows that in many instances there is an accompanying evolution of energy, from the changing system, in one form or other, either as heat, or light, or as electrical currents. In other cases to produce a chemical change expenditure of energy is necessary.

What may be the nature of the chemical force or affinity that acts between atoms is not known, but it is characterised from gravitative force by this difference, that whereas gravitation acts upon all kinds of matter alike, depending merely on the masses of the bodies, chemical attraction or affinity depends upon the kinds of matter that are presented to each other, as well as upon the conditions under which the bodies are brought together; in other words, it is an elective attraction modifiable by circumstances. For instance, at a red heat metallic iron is oxidised by water vapour and hydrogen is set at liberty, but at a lower temperature oxide of iron is reduced by hydrogen with the formation of metallic iron and water vapour; a mixture of hydrogen and chlorine will remain unchanged for any length of time in darkness, but exposure to sunlight will cause almost instantaneous combination, and the resulting compound (hydrochloride) may be again converted into its original constituents by heat. If to a solution of silver nitrate a piece of metallic copper be added, metallic silver is p.p.d., and copper nitrate formed; and if now to the

copper nitrate a piece of zinc or iron be added, metallic copper is *ppd.*, and zinc or iron nitrate is formed.

These illustrations are sufficient to show the relativity of chemical affinity as depending both upon the conditions to which the system is subjected as well as upon the qualities of the materials.

Under whatever conditions a chemical system may exist in which a change is happening, the atomic forces at work will continue to act until a state of more or less stable equilibrium is reached, after which no further action will take place; and the ultimate limit reached will depend upon (1) the relative quantities of the reacting bodies; and (2) the conditions to which the system is subjected. As the system passes from the initial to the final configuration there will be a loss or gain of energy equal in amount to the difference between the total energy of the system in the two states. The rate at which the change takes place will depend also upon the same two circumstances. These two statements amount to this; that, representing a chemical change by the equation  $A + B = A' + B'$ , all the atomic forces at work producing the transformation have not invariably the same ratios, but that the ratios vary with variations in the conditions as regards heat, light, &c.; and, consequently, any determinations of the relative affinities of the members of the system can only be looked upon as expressing certain ratios that hold good under special conditions. The final state reached by the system, and the rate at which the change progresses towards that state, vary with the relative masses of the reacting bodies, other things being equal, although the atomic forces or the affinities remain the same. In other words the final configuration, and the speed of attaining it, are each a function of the reacting masses and of the atomic forces, the latter being a function of the physical conditions to which the system is subjected.

The phenomena of dissociation furnish many examples of these facts; as do also those systems which are limited by inverse actions and do not properly come under the term dissociation, wherein both the masses of the constituents as well as the conditions, especially as regards heat, influence the change in its amount and rate. The great field offered for investigation by fractional *pptn.* will, no doubt, afford many striking instances of the variations of the affinity values under diverse circumstances when the subject is worked out.

From the foregoing considerations it is clear that a chemical system may or may not undergo change by virtue of any intrinsic forces acting among the constituents, but that such will happen only according to the conditions to which it is subjected. Reactions which at moderate temperatures take place with evolution of much energy may be completely suspended by lowering or increasing the temperature, excluding light, or altering the pressure; in other words, the forces or affinities resisting change, if greater than those tending to produce an alteration under some circumstances, may be reversed when these circumstances are altered.

There are, however, a number of interesting examples in which the stability of a system seems to be overturned by the mere presence

of an extraneous body which itself undergoes no apparent change. For instance, oxygen and  $\text{SO}_2$  do not combine when moderately heated, but if passed over spongy platinum combination readily occurs. Sometimes again the intermediate body does undergo change, as when chlorine is passed over a strongly heated mixture of carbon and silica, whereas without the addition of carbon the silica is not acted upon by the chlorine; or, platinum, which itself is insoluble in nitric acid, may be rendered soluble in the same acid by alloying it with silver (*v. post*, Catalytic changes, p. 750).

Some equally remarkable instances of the apparent necessity of the presence of a third body in order to bring about chemical action between two others have been noticed. Wanklyn (*C. J.* 20, 271) found that perfectly dry chlorine gas has no action upon metallic sodium. Couper (*C. J.* 43, 153), starting from Wanklyn's observation, has examined the action of dry chlorine on several metals that are acted upon vigorously by the moist gas. He found that dry chlorine has no perceptible action on Dutch metal, whereas with the moist gas combination takes place, with production of heat and light; or on touching the metallic surface when in an atmosphere of dry chlorine with a drop of water, instant combination occurs. Couper examined a number of metals in the same way with the following results: the chlorine gas used was allowed to stand over  $\text{CaCl}_2$  for several days to thoroughly dry it. Zinc, and magnesium, showed no action; silver, slight action; bismuth, combination slow; arsenic, antimony, and tin, rapidly acted upon. It is worthy of note that these last three metals form volatile chlorides liquid at ordinary temperatures. With mercury, combination equally rapid, with dry or moist chlorine. Potassium showed slight action, probably due to adhering  $\text{KHO}$ ; with proper precautions against moisture, action was slow. Dixon (*T.* 1881, 617) has observed a somewhat analogous fact relating to the combination of gases under the influence of the electric spark. He has shown that if a mixture of  $\text{CO}$  and  $\text{O}$  be perfectly dried by  $\text{P}_2\text{O}_5$ , and be then subjected to the spark from a large Leyden jar or a Ruhmkorff's coil, union does not take place; if, however, the slightest trace of moisture be admitted to the mixture, and the spark again made to pass, combination occurs. The hypothesis Dixon advances to account for these facts is that the intervention of water molecules is necessary to bring about combination, a molecule of water being decomposed under the influence of the spark by one of carbonic oxide to form carbonic acid and free hydrogen, the latter in its turn combining with the oxygen to form water; this cycle of operations being represented by the equations  $\text{H}_2\text{O} + \text{CO} = \text{H}_2 + \text{CO}_2$ ;  $\text{H}_2 + \text{O} = \text{H}_2\text{O}$ ; consequently a comparatively small number of water molecules are necessary to effect complete combustion. (See also *C. J.* 49, 94.) Phosphorus and carbon have been shown by Baker (*C. J.* 47, 349) to combine with oxygen less energetically in the absence of moisture than when moisture is present; and Ramsay and Young (*C. J.* 45, 93) observed that if a mixture of dry  $\text{F}$  and  $\text{N}$  is passed through a tube containing iron filings at a red heat no

ammonia is formed, with the moist gases, however, a trace of  $\text{NH}_3$  is obtained.

ALLOTROPIC CHANGE.

Several of the elementary bodies are known to exist in two or more different modifications, such for instance as sulphur, selenium, carbon, phosphorus, and oxygen; the several forms of each element exhibit more or less strongly marked differences in chemical as well as physical properties. It is probable that such different modifications of one elementary body consist, as in the case of oxygen and ozone, of different atomic groupings or aggregates of atoms. The means by which the change from one modification of an element to another is brought about are various. Oxygen is converted into ozone by the electric spark or 'silent discharge,' and ozone is changed again into oxygen by heat; yellow phosphorus is converted into the red modification either by light or by heat, and the red modification is again reconverted into yellow phosphorus at a higher temperature; sulphur and selenium undergo several changes under the influence of heat; in the case of carbon, the conditions necessary to bring about metamorphoses are not fully known.

The study of certain isomeric compound bodies (*v. ISOMERISM*) has shown that the transformation of one isomeric into another is, in some cases, somewhat analogous to the phenomena of dissociation. If solid paracyanogen  $(\text{CN})_2$  is heated in a closed vessel to  $860^\circ$  it is entirely converted into cyanogen gas  $(\text{CN})_2$ ; the pressure increases until the gas condenses and is liquefied on the cooler parts of the apparatus. At temperatures below  $500^\circ$  little or no decomposition occurs. As the paracyanogen is heated above this temperature a slow transformation takes place into gaseous cyanogen, and the transformation continues until the pressure of the cyanogen gas attains a certain definite limit beyond which it does not rise, and there is no further evolution of gas. Exhausting the apparatus and maintaining the temperature, the pressure again rises to its previous limit and remains stationary however long the heating is continued. For every such temperature there is a maximum pressure reached which limits the further decomposition of the paracyanogen into gaseous cyanogen. If now when the pressure has attained its limit, at a given temperature, a quantity of cyanogen gas is forced into the apparatus, the pressure slowly falls to the initial limit with the transformation of gaseous cyanogen into solid paracyanogen. Troost and Hautefeuille (*C. R.* 66, 735, 795) have found the following values for these pressures of transformation at different temperatures:

Temp.	Pressure of transformation.
502°	54° mm.
506	56 "
559	123 "
575	129 "
587	187 "
599	275 "
601	318 "
629	868 "
640	1310 "

The transformation of solid paracyanogen into gaseous cyanogen is seen to be analogous to the volatilisation of a liquid in presence of its own vapour; but the formation of red phosphorus from the yellow material or *vice-versa* is a more complex process. If a quantity of yellow phosphorus is heated in a closed vessel (say to  $500^\circ$ ), the mass of phosphorus being more than sufficient to volatilise in the space, a maximum pressure is quickly attained. After a time the pressure gradually falls, more or less quickly according to the temperature, till it reaches a minimum at which it remains constant. Provided there is no change of temperature, the vapour of the phosphorus is gradually converted into the red modification which condenses on the sides of the apparatus. If the quantity of phosphorus introduced into the apparatus is just sufficient to volatilise and fill the vessel with vapour at the first pressure (the heating being continued), red phosphorus begins to form after a time, and the pressure continues to fall until the minimum limit is reached as before. If, however, only sufficient ordinary phosphorus is used to fill the apparatus with vapour at the lower limit of pressure, no red phosphorus is formed, however long the heating may be continued. These two pressures—the maximum first attained, and the final minimum limiting the transformation of yellow into red phosphorus—depend solely upon the temperature. Troost and Hautefeuille (*A. Ch.* [5] 2, 153) found the following numbers relating to these phenomena:

Temp.	Pressure of vapour of P limiting the transformation	Maximum pressure of P vapour first produced
360°	12 atms.	3.2 atms.
440	1.75 "	7.5 "
487	6.80 "	—
494	— "	18 "
503	— "	21.9 "
510	10.8 "	—
511	— "	26.2 "
531	16 "	—
550	31 "	—
547	56 "	—

The rates at which the transformation takes place as well as other phenomena exhibited during the change have been studied by Lemoine (*A. Ch.* [4] 24, 194). He gives the following numbers illustrative of the progress of the change in time:

Ordinary P per litre. Grams.	Quantities of ordinary P remaining at $410^\circ$ , after							
	mins.	1 h.	2 h.	8 h.	17 h.	24 h.	32 h.	4 h.
2.9	—	—	—	2.9	—	—	—	—
5.9	—	—	—	5.3	—	—	4.0	4.7
16.0	—	—	—	5.0	—	—	—	—
24.0 (Hittorf)	5.5	11.1	7.0	4.4	—	—	—	—
30.5	—	5.4	4.0	3.7	3.6	—	—	—

Lemoine (*C. R.* 73, 990) has given a mathematical theory of the changes that red or yellow phosphorus undergoes when heated in a closed vessel, and has compared his formulæ with the results of experiment. Let  $P$  be the total mass

of material introduced into a space  $v$ , and let  $y_t$  be the mass of yellow phosphorus formed or existing at time  $t$ ; if the red phosphorus be supposed to remain in the same state of division throughout, its free surface will be sensibly proportional to its mass  $r-y$ . The quantity of yellow phosphorus evolved,  $\delta y_1$ , in time  $\delta t$  is equal to  $a(r-y)\delta t$ , and the quantity of the ordinary phosphorus,  $\delta y_2$ , transformed into the red modification in the same time is  $b(r-y)\delta t$ ; the total effect is therefore the difference between these two quantities, or

$$dy = \delta y_1 - \delta y_2 = a(r-y) - b(r-y)\delta t$$

which may be written  $\frac{dy}{dt} = f(g-y)(h-y)$ , representing the rate of change in terms of the ordinary phosphorus existing.

For further account of Allotropic Changes v. ALLOTHROPY.

#### INFLUENCE OF PRESSURE ON GASEOUS CHANGES.

Many bodies when subjected to the influence of heat in the gaseous state, undergo marked changes either in their physical or chemical properties, or in both; such changes result more particularly in a diminution of molecular density or a disruption of molecular structure. Among such bodies may be cited, mercurous chloride, chloral hydrate, phosphoric chloride, hydriodic acid, nitric peroxide, hydric selenide, amyl bromide, and acetic acid. In the case of some of these bodies the changes in question have been proved to be the accompaniment of disruption or dissociation of their molecules (v. DISSOCIATION); in other cases, such as nitric peroxide and acetic acid, there is no complete proof that the changes in density which these bodies suffer when heated in the gaseous state are really occasioned by a dissociation of their molecules, or are due to the fact of their vapours not obeying the dilatation-law even when sufficiently far removed from the liquid state as to place them under the category of gases. Considered from these two points of view, it is evident that the dilatation of a gas under the influence of heat may be of a twofold character, arising from two distinctly separate causes; firstly, the expansion may be purely physical, varying or not according to the dilatation-law, and secondly, there may be expansion as the accompaniment of a chemical change, viz., separation of the gaseous molecules into simpler groups of atoms. An observed variation of density at different temperatures may be produced by either of these two causes, or by both combined, and it becomes therefore a matter of great importance to be able if possible to discriminate these two actions, and to say to which of them the observed results are to be ascribed. If it could be shown that a diminution of pressure produced the same variation in the densities of certain gases as has been observed under the influence of heat, a great point would be gained in favour of the dissociation-theory in settling the cases under dispute. It would seem possible that a discrimination between the two possible phenomena accounting for abnormal densities might be made by introducing the element of time into such

investigations. To make this clear, take the case of nitrogen tetroxide, whose vapour density at low temperatures has been found to be approximately represented by the formula  $N_2O_4$ , while at high temperatures it corresponds to  $NO_2$  (the vapour densities being 3.18 and 1.59 respectively). Now Troost (*C. R.* 86, 1394) found the vapour density of nitrogen tetroxide at 27° and at low pressures to be as follows:

Pressure.	Density.
35 mm.	1.6
16 "	1.59 ( $NO_2 = 1.59$ ).

These results show that the same change takes place under diminished pressure as occurs under the influence of heat at ordinary atmospheric pressures; that is to say, these numbers indicate that, if the observed changes in density are due to dissociation of the molecules  $N_2O_4$  into the molecules  $NO_2$ , then under a pressure  $p$  the ratio of the number of molecules of  $N_2O_4$  to  $NO_2$  is different from the ratio when the pressure is altered to  $p'$ , temperature being the same in each case. The proof of this assertion is of considerable importance in the theory of dissociation; whether the change in density is or is not to be attributed to the supposed fact, that the gas  $N_2O_4$  forms an exception to the dilatation-law, would seem to be capable of indisputable proof by introducing the element of time into the experiments. If the gas  $N_2O_4$  is really dissociated into  $NO_2$  under diminished pressure, 2 vols.  $N_2O_4$  would give 4 vols.  $NO_2$ ; now, by the kinetic theory of gases it is conceivable that this dissociation would take place practically instantaneously when the temperature was increased or the pressure was diminished, whereas on reversing the process the molecules of  $NO_2$  would require some time before meeting with the requisite number of partners to re-form the molecules of  $N_2O_4$ . Such an experiment might form a crucial test of the truth of the dissociation-hypothesis for this particular gas, and it might also be applied to other cases, for it is scarcely conceivable that the coefficient of dilatation of a gas should alter in time. Natanson (*W.* 24, 454) has determined the ratio between the specific heats of nitrogen tetroxide by means of Kundt's dust-figure method; his results seem to show that as the pressure decreases this gas passes from a more to a less complex molecular structure.

In the determination of the vapour densities of several bodies whose abnormal dilatations are almost undoubtedly to be ascribed to the disruption or dissociation of their molecular structures, the influence of time on the phenomenon has been several times observed, and has been made the subject of investigation by Naumann for the particular case of ammonium carbamate (v. next page).

Wurtz (*C. R.* 60, 729), when determining the vapour density of amyl bromide (b.p. 113°) between 153° and 260°, noticed that when the vapour was suddenly heated to 225° the density was 1.69, whereas in another experiment when the vapour had been maintained at this temperature for ten minutes the density was 3.68. These results show undoubtedly that the diminution in density, or the dissociation produced by heating, required time to be effected, and hence was

due to a chemical change and not to a variation in the coefficient of dilatation of the gas.

Naumann (A. 160, 1) studied the influence of time on the dissociation and re-formation of ammonium carbamate; the following tables illustrate the general bearing of his experiments:—

Speed of dissociation of  $\text{NH}_4\text{CO}_2$  at  $46^\circ$ .

Pressure under the dissociation-pressure, which = 354 mm.	Increase of pressure	Time of increase

In these two examples it is seen that, starting with a mass of solid ammonium carbamate (Naumann showed by his experiments that at all temperatures the gas evolved consists of  $2\text{NH}_3 + \text{CO}_2$ ) and suddenly increasing the temperature, a considerable time is required before the normal pressure of dissociation corresponding to that temperature is reached. In like manner, by suddenly diminishing the temperature, the recombination of the ammonia with the carbon dioxide to form the solid  $(\text{NH}_4)_2\text{CO}_2$  does not take place instantaneously, but a considerable time elapses before the pressure corresponding to the lower temperature is arrived at. Although analogous in some respects to the volatilisation and condensation of a liquid, the phenomena exhibited by  $(\text{NH}_4)_2\text{CO}_2$  when heated are characterised by their greater slowness.

In experiments relating to vapours of varying densities—such as those of Troost on acetic acid and nitric tetroxide at low pressures—it is important to determine whether diminution of pressure acts in a manner similar to that of heat

in bringing about dissociation, or disruption, of the molecules of the gas. By introducing the element of time into the experiments, and by suddenly varying the pressure, dissociation might be shown to occur in the case of nitric tetroxide as already remarked, the process in this case being doubtless reversible; whereas with say, ozone, or a mixture of ozone and oxygen, the amount of change produced by increasing the volume, say, twenty-fold, could be determined by the usual methods of analysis (cf. *Also Dissociation, and Equilibrium Chemical*).

#### CHEMICAL SYSTEMS.

Considering the three physical states in which bodies are capable of undergoing chemical change, either as gases, liquids, or solids, it is evident that there are two distinct kinds or classes of chemical systems possible, according to the states in which the active substances exist, and which may be termed heterogeneous and homogeneous systems. The former name is applied to all reactions in which the active members of the system are in different physical states, a solid and a liquid, or a solid and a gas, or a liquid and a gas; as examples of each of these may be mentioned the action of acids on metals or on carbonates, the dissociation of calcic carbonate or ammonic carbamate by heat, and the oxidising action of free oxygen on solutions of stannous or ferrous salts. By homogeneous systems are to be understood those in which all the active members exist in the same physical state, either as liquids or gases; it is inconceivable that two solid bodies, however finely powdered and well mixed, could come under this category. Examples of homogeneous systems are shown in the numerous etherification processes, the oxidising action of potassic chlorate on ferrous salts, the action of oxalic acid on potassic permanganate, among liquids, and for gaseous systems, the action of iodine or selenium on hydrogen, and the influence of light on a mixture of chlorine and hydrogen or on gaseous hydriodic acid. Many valuable facts have been brought out by the study of heterogeneous chemical systems, especially as regards dissociation-phenomena; but the great field in which the most fundamental facts concerning chemical action will be gathered is naturally that embracing homogeneous systems, for here the most intimate contact exists among the acting substances, affording free play to the various chemical forces at work, and the secondary physical changes which interfere with the primary chemical change are reduced to a minimum.

**Heterogeneous Systems.**—Gladstone and Tribe (Pr. 19, 498) have investigated the rate at which a more positive metal immersed in a solution of a salt of a less positive one displaces the latter, and the relation which exists between the rate of action and the mass of salt in the solution. Employing a solution of argentic nitrate, the displacing metal being copper, and allowing the action to continue for ten minutes under varying conditions of concentration, they found that by doubling the amount of silver salt in solution the amount of action that took place during this interval of time was trebled. Zinc and cupric chloride, zinc and cupric sulphate, zinc and lead nitrate, iron and cupric sulphate,

and other combinations, showed in every case, when the solutions were sufficiently diluted, that this 2-3 law holds good. Expressed algebraically, if  $y$  be the mass of metal dissolved, and  $x$  the concentration of the solution, then the above

2-3 law is  $y = ax^{\frac{1}{3}}$  where  $a$  is a constant.

These experiments have been repeated and extended by Langley (*C. J.* 45, 663), who confirms the truth of Gladstone's law; but when the method of experimenting is modified, as by continually moving the metal about in the solution or by brushing its surface so as to keep the solution uniform throughout, Langley considers that the rate of action is proportional solely to the amount of salt in solution. Moreover, Langley's experiments indicate that the law observed by Gladstone and Tribe arises from two causes, viz., chemical action, and gravitative action, the latter producing slow currents through the solution because of the changing densities of the original salts and of those which are produced in the change.

In studying the rate of evolution of carbon dioxide from marble by the action of acids, Bojowski and Kajander (*B.* 10, 31) found that the rate of action is proportional to the concentration of the acid, but varies according to the nature of the acid employed; moreover, they concluded that, for the three acids HCl, HBr, and HNO<sub>3</sub>, the speed of the action is inversely proportional to the molecular weights of the acids when the solutions are of equal degrees of concentration. Pawlewski (*B.* 13, 334) has continued these experiments, employing different carbonates (BaCO<sub>3</sub>, CaCO<sub>3</sub>, SrCO<sub>3</sub>) with the same acid; although his results are not very regular, yet he considers them sufficient to show that the speed of the reaction is inversely proportional, not to the molecular weights of the carbonates, but to the atomic weights of the metals whose carbonates were employed.

Of a somewhat similar nature to the experiments of Gladstone and Tribe is the work of Thorpe (*C. J.* 41, 287) on the behaviour of zinc, magnesium, and iron, as reducing agents, with acidulated solutions of ferric sulphate. Known weights of these three metals in the form of thin foil were introduced into acidified solutions of ferric sulphate, and the amount of reduction effected—part of the liberated hydrogen coming off as gas—under varying conditions of temperature, amount of free acid, and strength of the ferric solution, was determined. The results obtained showed that the reduction effected when a given mass of zinc dissolves in an acidified solution of ferric sulphate increases with increase of temperature, other conditions being the same. Provided a sufficiency of acid to dissolve the zinc be present, the maximum reducing action is obtained by concentrating the ferric sulphate solution, and diminishing the amount of free acid.

When magnesium is employed the reduction effected is scarcely one-fourth of that for zinc, while the time required for solution is comparatively very short; by diminishing the quantity of free acid the amount of reduction effected is increased. The diminution in the rate of solution with a decrease in the quantity of free acid

was found to be much greater in the case of magnesium than in that of zinc; with zinc the rates were approximately in the ratios 1:1.5:2, and, under like conditions with magnesium, the rates were as 1:6:36. When the ferric sulphate is reduced by iron, the rate of solution becomes extremely slow, and the reducing action appears to decrease with increase of temperature. These reduction experiments, considered as a whole, seem to be in harmony with the view that the reducing action of so-called nascent hydrogen is connected with the existence of atoms, as distinguished from molecules of this gas; and that any conditions which tend to prevent the mutual combination of these atoms tend also to increase the amount of reduction effected by the hydrogen.

When phosphorus oxychloride acts upon certain nitrates, it has been found that the ratio between the chlorine and phosphoric pentoxide in the residue obtained after all action has ceased has a certain definite value. Mills (*P. M.* [4] 40, 134, and 44, 506), who has studied this reaction for several nitrates, has designated these ratios by the symbol  $\alpha$ , or

$$\alpha = \frac{\text{weight of chlorine}}{\text{weight of } P_2O_5}$$

rather he has taken  $\alpha$  as =  $\frac{\text{weight of } Cl}{\text{weight of } P_2O_5}$ . When one nitrate fixes more chlorine, per unit of P<sub>2</sub>O<sub>5</sub>, than another nitrate, Mill says that the affinity of the former is greater than that of the latter nitrate; inasmuch as this chlorinefixing action can be measured for several nitrates, the values of  $\alpha$ , on Mill's view, represent the 'elective attractions' of the nitrates.

If  $\alpha$  be divided by the formula-weights,  $\Sigma$ , of the several nitrates, calculated to a uniform mass of NO<sub>2</sub>, the following numbers (under  $q$ ) are obtained:—

	$\alpha$	$\Sigma$	$q$
Thallous nitrate	8.78	265.30	30.29
Silver "	5.48	239.94	31.01
Lead "	5.17	165.56	32.02
Rubidium "	2.38	147.40	61.93
Cæsium "	2.21	195.01	88.24
Potassium "	1.99	101.14	50.82
Sodium "	1.70	86.05	50.03
Lithium "	1.60	69.00	42.86

These numbers show that the affinity-coefficients are directly proportional to the formula-weights of the nitrates, and that (with one exception)  $\alpha$  and  $\Sigma$  increase and diminish in regular order. The quotients,  $q$ , therefore, represent the masses of nitrates which correspond with what Mill calls a 'unit of elective attraction.'

#### Chemical Systems of limited action.

When a chemical reaction is expressed symbolically either as  $AB + CD = AC + BD$  or  $A' + B' = C'$ , it is usually understood that for the complete decomposition of the mass AB all that is necessary is to bring it into suitable contact with the definite mass of the second body CD, or that the

nages: A' if presented to B' under proper conditions will unite with it to form C'. In many chemical changes this is true, at least within the limits of experimental error, and if sufficient time be given; and it may be said that many processes of quantitative chemical analyses are based on this assumption. There are, however, many instances known in which the statement does not hold good. For example, if mol. weights of ethylic alcohol and acetic acid are mixed and heated for some time, say at 100°, only about 66 p.c. of the total action possible takes place, no matter how long the operation is allowed to continue; or again, if mol. weights of iodine and hydrogen are heated at 440° in a closed vessel, even after an indefinitely long period of time there will still exist a certain fraction of these elements uncombined. The limitation of these and many other similar changes appears to be due to the fact that the products of the first action tend, under the conditions of the experiment, to re-form the original substances, and the two reactions proceed simultaneously with different degrees of intensity, depending upon the masses of material, until a stage is reached at which a state of equilibrium is attained, the first action at this stage being balanced by the second. The mutual action of alcohol and acetic acid would thus be represented by the equation—

The theory of such limited actions was formulated by Guldberg and Waage, in 1867 (*Études sur les Affinités chimiques*) and applied by them to the determination of the 'coefficients of affinity' for several reactions. These chemists concluded from the results of their experiments that in a system undergoing change the amount of action in a unit of time between two or more active bodies—in other words, the rate of the change—is proportional to the product of the active masses. This same assumption was made by Berthelot in 1862, based on the results of his etherification experiments; and in 1866 Harcourt and Esson showed that for certain chemical systems the rate of change is proportional to the product of the active masses of the changing bodies. In the above statements the 'active masses' of the various bodies means the number of equivalents of each present in the reacting system. There are instances, however, in which bodies introduced into a chemical system either accelerate or retard the reaction without themselves undergoing change (*v. post*, p. 714). Guldberg and Waage assume that, in the reaction  $A + B = A' + B'$ , if the masses of A and B be  $p$  and  $q$ , then the force tending to produce the change varies as the product  $pq$ , whatever may be the kinds of matter; for two particular substances this force is equal to  $\kappa pq$ , where  $\kappa$  is the 'coefficient of affinity' depending upon the kinds of matter, and probably upon the conditions of the experiment (*v. ante* and also AFFINITY, pp. 70-75). This, however, is not the only force acting; there are others of a secondary character tending to retard or accelerate the formation of A' and B'. Neglecting these secondary forces for the present, let the masses of A' and B' be  $p'$  and  $q'$ , and the coefficient of affinity for the reverse

action  $A' + B' = A + B$  be  $\kappa'$ , then the force tending to re-form A and B equals  $\kappa' p' q'$ . When equilibrium is attained these two forces are equal, or  $\kappa pq = \kappa' p' q'$ , so that if the four quantities  $p, q, p', q'$ , are determined experimentally, the ratio of the coefficients of affinity may be found.

Expressed in another way, if  $p, q, p', q'$ , be the number of equivalents of the four substances in the system at the beginning of the reaction, and if  $x$  be the number of equivalents of P and Q transformed into  $p'$  and  $q'$  when equilibrium is reached, or no further change takes place in the system, all expressed in terms of unit volume, then  $p = p - x$ ,  $q = q - x$ ,  $p' = p' + x$ , and  $q' = q' + x$ ; inserting these values, the equation becomes  $\kappa(p-x)(q-x) = \kappa'(p'+x)(q'+x)$ .

Such is the simplest representation of the theory of limited actions. The presence, however, of extraneous salts, or even the secondary actions among the four bodies themselves, doubtless materially influence the ultimate limit when a state of equilibrium is reached. For instance, if a body x be introduced into the system, Guldberg and Waage assume that the force produced by the action between x and A, and influencing the change between A and B, is proportional to the product of x and A, or is equal to  $ax$ , and they term  $a$  the 'coefficient of action.' Assuming that there are coefficients of action between all the four bodies—these coefficients being  $\alpha, b, c$ , and  $d$ , for A and A', A and B, B and A', and B and B', respectively, and  $\alpha', b', c', d'$ , for A' and A, B and A, A' and B, and B' and B, respectively—then the total force for the reaction between A and B will be equal to

$$\kappa pq + \alpha pp' + bpq' + \alpha' p'q + dqq',$$

and that between A' and B' will be equal to  $\kappa' p'q' + \alpha' p'p + b'pq' + c'p'q' + d'q'q'$ .

But that there may be equilibrium these forces must be equal. Writing  $a - a' = \alpha, b - b' = \beta$ , &c., the equation of equilibrium becomes

$$\kappa pq = \kappa' p'q' + \alpha pp' + bpq' + \alpha' p'q + \beta q'q'.$$

If it is desired to study the rate at which the reaction progresses, then this rate is assumed to be measured by the difference between the two forces or

$$\frac{dy}{dt} = \kappa pq - \kappa' p'q' - \alpha pp' - \beta pq' - \gamma p'q - \delta q'q'.$$

Owing to their complicated character, these equations for the limit or the rate of a chemical change are of little value from an experimental point of view; it would seem scarcely possible to determine the numerous secondary forces Guldberg and Waage introduce into their formulae. In such a case as the action between barium sulphate and potassium carbonate the secondary actions to be taken into account are between  $\text{BaSO}_4$  and  $\text{BaCO}_3$ ,  $\text{BaSO}_4$  and  $\text{K}_2\text{SO}_4$ ,  $\text{K}_2\text{CO}_3$  and  $\text{BaCO}_3$ ,  $\text{K}_2\text{CO}_3$  and  $\text{K}_2\text{SO}_4$ , and between the water and each of the four salts. For a full discussion of this theory in its simpler form applied to experimental results see Guldberg and Waage, *J. pr.* [2] 19, 69 (*v. also* AFFINITY, p. 75).

Berthelot and Saint-Gilles (*A. Ch.* [3] 65 385; 66, 1; 68, 225) were the first to make a complete study of the reactions between carbon acids and alcohols, as regards the influence exerted by variations of temperature, pressure

amounts of material, and time. They found that these reactions are characterised by three important features: (1) the combination proceeds slowly, with a velocity depending upon the influences to which the system is submitted; (2) the combination is never complete, however long the duration of contact; (3) the proportion of ethereal salt formed under different conditions always tends towards a limit.

The inverse action limiting the formation of the ethereal salt, viz. its decomposition by the water formed during the reaction, was found to be much less rapid than the combination. In other words, if two systems are employed—one consisting of ethylic alcohol and acetic acid, the other of ethylic acetate and water—all in equivalent proportions, the first of these will attain the limit of equilibrium more quickly than the second under like conditions. Berthelot (*A. Ch.* [3] 66, 113) concluded that in the formation of the ethereal salts 'the quantities of acid and alcohol that combine at each instant are proportional to the product of the reacting masses.' He gave the formula for expressing

the rate of formation as  $\frac{dy}{dt} = \nu \mu \left(1 - \frac{y}{l}\right)^2$ , for

equivalent quantities of alcohol and acid, where  $l$  is the limit, which for acetic acid is = 66.5.

According to the theory of mass-action, the rates of formation of ethereal salts, as well as the magnitude of the limits, ought to be increased by an increase in either the amount of alcohol or of acid. As regards the ultimate limits, this was found to be true by Berthelot and Saint-Gilles, but for the speed of etherification they found that with  $n$  equivalents of alcohol and one of acid there was (at least for part of the course) little or no increase over that for equivalent quantities; in fact, a diminution in the rate was observed. On the other hand, with  $n$  equivalents of acid and one of alcohol the rate of etherification was greatly accelerated. The following two tables illustrate these points (*A. Ch.* [3] 66, 90, 98):—

1 eq. acetic acid +  $n$  eq. alcohol. Temp. 100°.

	$n=1$ , acid=100, limit=100		$n=2$ , acid=100, limit=100		$n=5$ , acid=100, limit=100	
4 h.	25.8	38.8	27.8	33.8	17.5	19.3
15 "	47.4	71.3	44.0	53.2	31.3	34.5
33 "	60.6	91.1	72.2	87.1	72.2	79.4

1 eq. alcohol +  $n$  eq. acid. Temp. 100°.

	$n=1$ , acid=100, limit=100		$n=2$ , acid=100, limit=100		$n=5$ , acid=100, limit=100	
4 h.	25.8	38.8	47.1	54.9	57.6	59.4
15 "	47.4	71.3	74.4	86.7	96.6	100
33 "	60.6	91.1	79.2	92.5	96.6	100

The variation produced in the limit, or maximum amount of ethereal salt formed, by employing excess of one or other of the constituents is illustrated by the following tables (*A. Ch.* [3] 68, 274, 286):—

1 eq. acid + $n$ eqs. alcohol.	$n$ limit	$n$ eqs. acid + 1 eq. alcohol.	$n$ limit
1.0	66.5 p.c.	1.0	66.5 p.c.

12.0	93.2	.08	7.8
19.0	95.6	.05	5.0
500.0	neutral to litmus.		

The action of inorganic acids on alcohols has been investigated by Villiers (*A. Ch.* [5] 21, 72); but in these processes secondary reactions that are liable to occur complicate matters somewhat. With a given alcohol, the speeds of etherification of the acids HI, HBr, HCl, and  $H_2SO_4$  were found to be widely different. HI etherifies more quickly than HBr, and each more quickly than acetic acid; whereas HCl acts with extreme slowness, even much more slowly than acetic acid.  $H_2SO_4$  etherifies almost immediately under ordinary conditions, but the speed is diminished by dilution, as well as by lowering the temperature. The etherification limits at 100° are different for the three hydracids, and are greater than the corresponding limits at lower temperatures. The limits also depend upon the proportion of water which exists in the initial mixture, but while the limit diminishes in the case of organic acids in a continuous manner as the water increases, without actually becoming *nil*, the etherification by hydracids ceases completely with a certain dilution, and this limit of dilution is not fixed but rises rapidly as the temperature rises. With  $H_2SO_4$ , the etherification is completely stopped with a certain proportion of water, but, contrary to what occurs with the hydracids, increasing the temperature to 100° does not cause the reaction to take place. From a consideration of the work of Berthelot and Saint-Gilles on the rate and conditions limiting the etherification of alcohols by organic acids, it would seem natural to conclude that the application of the methods employed by these chemists to the various cases of isomerism among alcohols and acids would yield important results relating to the structure of such bodies. For the purpose of discovering whether any relation exists between the rate and limit of etherification and the isomeric structure of either of the two active bodies taking part in the reaction—Menschutkin (*A. Ch.* [5] 20, 289; 23, 14; *J. pr.* [2] 24, 49; 25, 193) has made an elaborate study of the action of organic acids on alcohols. In order to render all the results comparable with each other it was necessary to assume two standards for reference, one for the alcohols and another for the acids. Methyl alcohol was chosen as the standard alcohol; and formic acid as the standard acid. The two characteristics chosen for measurement were (1) the initial speed of etherification, or the amount of action that takes place in the first hour, and (2) the final limit of the process; these Menschutkin terms the 'etherification-data.' For the 'methyl-alcohol' system Menschutkin took the limit as equal to 100; that is to say, out of equal numbers of molecules of methyl

alcohol and acetic acid (in this case 14) only 100 molecules were converted into ethylic acetate when the system reached a state of equilibrium of these 100 molecules, 80 were formed during the first hour of action.

The following table contains the 'etherification-data' for the primary alcohols employed:—

Alcohol	Speed	Limit
Methylic, $\text{CH}_3\text{CH}_2\text{OH}$	80	100
Ethylic, $\text{CH}_3\text{CH}_2\text{OH}$	67.3	95.6
Propylic, $\text{C}_3\text{H}_7\text{CH}_2\text{OH}$	66.9	96
Butylic, $\text{C}_4\text{H}_9\text{CH}_2\text{OH}$	67.4	96.6
Octylic, $\text{C}_8\text{H}_{17}\text{CH}_2\text{OH}$	67.0	96.6

The influence of isomerism on etherification among the primary alcohols was investigated for the case of isobutylic alcohol; the data obtained were

Isobutylic,  $\text{C}_3\text{H}_7\text{CH}_2\text{OH}$ , speed = 64.6 limit = 96.6. These numbers show that the limit is unaffected, but that there is a small decrease in the speed. The unsaturated primary alcohols showed less facility for forming ethers, the reaction in their case progressing much less rapidly, as the following numbers show:—

	speed	limit
Allylic alcohol, $\text{C}_3\text{H}_5\text{CH}_2\text{OH}$	51.9	85.3
Propargylic alcohol, $\text{C}_3\text{H}_3\text{CH}_2\text{OH}$	29.5	?
Benzyl alcohol, $\text{C}_6\text{H}_5\text{CH}_2\text{OH}$	54.6	87.3

For the secondary alcohols, the phenols, and some other alcohols, the following etherification-data were obtained:—

	Speed	Limit
Dimethyl carbinol $(\text{CH}_3)_2\text{CHOH}$	38.2	86.9
Methyl ethyl " $(\text{CH}_3)(\text{C}_2\text{H}_5)\text{CHOH}$	32.5	85.2
Diethyl " $(\text{C}_2\text{H}_5)_2\text{CHOH}$	24.3	84.2
Isopropyl methyl " $(\text{CH}_3)(\text{C}_3\text{H}_7)\text{CHOH}$	27.2	85.2
Isobutyl ethyl " $(\text{C}_2\text{H}_5)(\text{C}_4\text{H}_9)\text{CHOH}$	26.9	?
Hexyl methyl " $(\text{CH}_3)(\text{C}_6\text{H}_{13})\text{CHOH}$	34.1	?
Ethyl vinyl " $(\text{C}_2\text{H}_5)(\text{C}_2\text{H}_3)\text{CHOH}$	23.8	75.1
Diethyl " $(\text{C}_2\text{H}_5)_2\text{CHOH}$	15.3	72
Rthyl phenyl " $(\text{C}_6\text{H}_5)(\text{C}_2\text{H}_5)\text{CHOH}$	27.2	?
Diphenyl " $(\text{C}_6\text{H}_5)_2\text{CHOH}$	31.6	?
Phenol " $\text{C}_6\text{H}_5\text{OH}$	2.0	2.4
Paracresol " $\text{C}_6\text{H}_4(\text{CH}_3)\text{OH}$	3.7	13.7
Thymol " $\text{C}_9\text{H}_7(\text{CH}_3)_2\text{OH}$	?	13.6
$\alpha$ -Naphthol " $\text{C}_{10}\text{H}_7\text{OH}$	1.4	8.8
Glycol " $\text{CH}_2\text{OHCH}_2\text{OH}$	61.7	77.4
Glycerin " $(\text{CH}_2\text{OH})_3$	52.2	66.2
Erythrite " $\text{C}_4\text{H}_8(\text{OH})_2$	34	57.6
Mannite " $\text{C}_6\text{H}_{12}(\text{OH})_6$	29.6	38

Menschutkin (*J. pr.* 25, 193) has also determined the initial speeds and limits for different organic acids, employing one alcohol (isobutylic), and taking formic acid as the standard of reference. The following results were obtained:—

Acid	Speed	Limit
Formic $\text{CH}_3\text{CO}_2\text{H}$	100	100
Acetic $\text{C}_2\text{H}_3\text{O}_2$	71.9	104.8
Propionic $\text{C}_3\text{H}_5\text{O}_2$	67.7	106.9
Butyric $\text{C}_4\text{H}_7\text{O}_2$	65.9	108.2
Caproic $\text{C}_6\text{H}_{11}\text{O}_2$	63.6	108.7
Caprylic $\text{C}_8\text{H}_{15}\text{O}_2$	50.0	110.3
Hydrosorbic $\text{C}_{10}\text{H}_{19}\text{O}_2$	69.7	100.4
Phenylacetic $\text{C}_8\text{H}_9\text{O}_2$	79.1	115
Phenylpropionic $\text{C}_{10}\text{H}_{11}\text{O}_2$	68.2	112.1
Dimethacetic $\text{CH}_3(\text{CH}_3)\text{CO}_2\text{H}$	43.4	108.2
Methethacetic $\text{CH}_3(\text{CH}_3)(\text{C}_2\text{H}_5)\text{CO}_2\text{H}$	30.3	114.8
Crotonic $\text{C}_4\text{H}_7\text{CO}_2\text{H}$	19.6	112.3
Cinnamic $\text{C}_9\text{H}_7(\text{C}_6\text{H}_5)\text{CO}_2\text{H}$	136.7	116.3
Trimethacetic $\text{C}_6\text{H}_5\text{O}_2$	11.8	113.1
Dimethethacetic $\text{C}_8\text{H}_{11}\text{O}_2$	4.8	115.4
Boric $\text{C}_2\text{H}_3\text{O}_3$	12.9	116.3

Acid	Speed	Limit
Benzic $\text{C}_6\text{H}_5\text{O}_2$	13.9	113.9
Nitrobenzoic $\text{C}_6\text{H}_4(\text{NO}_2)\text{O}_2$	40.1	114.3
Paratolyllic $\text{C}_6\text{H}_4\text{O}_2$	10.7	119.1
Umbellio $\text{C}_{10}\text{H}_7\text{O}_2$	10.1	118.1

From the foregoing numbers it is seen that the rates of etherification of the secondary acids are much less than those of the primary acids, but that the limits show only slight variations. The speeds of etherification of the tertiary acids are less than those of either the primary or secondary acids, but on the other hand the limits are greater. For a full discussion of the value of etherification-data as a means of determining isomerism among alcohols and acids see Menschutkin (*J. pr.* [2] 26, 103; also *Z. P. C.* 1, 611).

The theory of limited chemical reactions has been formulated in a simple manner by Van 't Hoff (*B.* 10, 669) for the particular case of etherification, but essentially in the same manner as Guldberg and Waage have done in their general treatment of this chemical problem. If the system initially consists of one equivalent of acetic acid,  $\kappa$  of alcohol, and  $q$  of water, then when the quantity  $\epsilon$  of ether has been formed, there will still remain of acid  $1 - \epsilon$  of alcohol  $\kappa - \epsilon$ , and of water  $q + \epsilon$ ; consequently the rate at which ether is still being formed is expressed by  $\text{C}_1(1 - \epsilon)(\kappa - \epsilon)$ , and the rate of decomposition of the already formed ether by the water by  $\text{C}_2\epsilon(q + \epsilon)$ . When equilibrium is attained these two expressions must be equal or,  $\text{C}_1(1 - \epsilon)(\kappa - \epsilon) = \text{C}_2\epsilon(q + \epsilon)$ . For equivalent quantities of acetic acid and ethylic alcohol,  $\kappa = 1$  and  $q = 0$ , Berthelot and St. Gilles found the limit to be about 66.6 p.c., or  $\epsilon = \frac{2}{3}$ . Inserting

these values in the equation, the ratio of the two constant  $\text{C}_1$  and  $\text{C}_2$  is found; or  $\text{C}_1 = 4\text{C}_2$ . The equation now becomes  $4(1 - \epsilon)(\kappa - \epsilon) = \epsilon(q + \epsilon)$  from which the maximum quantity of ether capable of being formed when various amounts of alcohol or water are employed can be calculated. For instance, if  $\kappa = \infty$ , i.e. if the alcohol is unlimited in amount,  $\epsilon = 1$ , that is, all the acid is changed into ethereal salt; if  $q = \infty$ , i.e. if the water is unlimited in amount,  $\epsilon = 0$ , or no ether is formed. These results are merely the extreme cases of what experiments have proved to be true between those limits of  $\kappa$  and  $q$  which have been tried.

**Formation of Acetanilide.**—In a study of the formation of acetanilide, according to the equation  $\text{C}_6\text{H}_5\text{NH}_2 + \text{C}_2\text{H}_3\text{O}_2 = \text{C}_6\text{H}_5(\text{C}_2\text{H}_3\text{O})\text{HN} + \text{H}_2\text{O}$ , Menschutkin (*J. pr.* 26, 208) found that, although in the processes of etherification the final limit of the reaction, attained after an indefinitely long interval of time is practically uninfluenced by change of temperature, in this example the limit is materially decreased as the temperature increases. The following results show this decrease:—

Temp.	Limit.
70°	85.05 p.c.
125°	83.11
135°	82.39
145°	81.23
155°	79.60

Another remarkable fact was noticed in this

reaction, and one which is apparently at variance with most experiments relating to the action of mass (see Bertholot's etherification experiment, *ante*). In any chemical system undergoing change, comprising two or more active bodies, the rate of change is generally accelerated (v. p. 74) by an increase in the amount of any of the active bodies, and this increase in the rate is more or less proportional to the quantity of active substance added. But in the formation of acetanilide, with a constant amount of acetic acid, an increase in the quantity of aniline retards the action, according to Menschutkin, although the final limit is increased as the theory of mass-action requires. The numbers under 'speed' showing this fact represent the amount of action after 15 mins.

Molecules aniline with one mol. acid	Speed	Limit
1	34.71	79.68
2	28.71	91.65
3	23.45	94.61
4	—	96.17
8	17.13	97.22

However, when the aniline remains constant and the acetic acid is increased, the law of mass-action appears in the normal way (v. also AFFINITY, p. 85).

Molecules acid with one mol. aniline	Speed	Limit
1	34.71	79.68
2	57.30	96.88
4	78.08	99.80

#### Division of a base between two acids.

When a mixture of two acids acts on a base, or two bases act on one acid, the two acids in the first case being more than sufficient to combine with the base, or the two bases in the second case with the single acid, it is usually granted that the base divides itself between the two acids or the acid between the two bases in definite ratios. Or if an acid acts upon a salt in solution, as nitric acid on potassic sulphate, a definite amount of change takes place resulting in this instance in the formation of potassic nitrate and sulphuric acid. If the ratios in which such divisions occur were known they might afford measures of the relative affinities of the acting bodies for the particular conditions of the experiments. Such ratios have been determined for a great many acids by Ostwald, with most important results. (For an account of this work v. AFFINITY.)

Pattison Muir (*C. J.* 33, 27; 35, 311; 36, 60) has studied the conditions affecting the equilibrium of certain chemical systems wherein pps. are formed, with the view of determining the relationship between the concentrations of the solutions, the ratios between the active bodies, and the influence of heat on the equilibrium ratios. An investigation somewhat similar to this was conducted by Morris (*A.* 213, 233).

#### Fractional Precipitation.

It has been shown (*ante*; and v. AFFINITY) that if a mixture of two acids is allowed to

act upon a single base, or of two bases on a single acid, the ratio in which the base divides itself between the two acids, or the acid between the two bases, depends upon the relative quantities or masses of the materials in the system, as well as upon the strength of the affinities acting between the several bodies. In like manner, if a pptant. is added to a solution, containing two or more salts of different metals, the mass of the pptant. being less than is required for complete ppn. of all the salts in the solution (being,

say,  $\frac{1}{\mu}$ th of the total necessary) then the ratios

of the quantities of the salts decomposed—or of the hydrates, carbonates, &c. formed—depends on (i) the relative masses of the substances in solution, (ii) the relative affinities of the salts or the basic powers of the oxides with reference to the pptant., and also (iii) on the fraction of the total material that is ppd.

This highly interesting subject of fractional ppn. has been as yet investigated but to a very slight extent; it would, however, seem to promise in the future a fertile field for the determination of what might be called the relative basic powers of different oxides or hydrates. If, for example, a solution contains two salts of different metals, the basic powers of whose oxides are different, and if a small fraction is ppd. (say as hydrate), there will be a tendency on the part of the less basic material to accumulate in the pp. in preference to the more basic, and this tendency will be greater as the difference between the basic powers is greater. If the basic powers differ but slightly, then the increase in the ratio of the less to the more basic material will progress very slowly by repeated application of the process of fractional ppn. If in the extreme case no such difference exists under the conditions of the experiment as regards temperature and quality of the pptant. (the ratio of the basic powers may and probably does vary with the temperature), then the ratio of the two materials in the small pp. will be the same as that in the original solution, and consequently, however frequently the process may be repeated on each fraction formed, no separation will be effected.

At the present time there are a number of elements known belonging to the earths, for the separation of which the only method that has yet been discovered is that of fractional ppn., or fractional fusion; in both cases the separation depends on the differences of the basic powers of the various bodies. Such, for instance, is the separation of the three elements, samarium, didymium, and lanthanum, from each other; or holmium, thulium, and erbium; & again terbium from yttrium. These separations are so extremely tedious, requiring the application of fractional ppn. to be repeated a very great number of times with but relatively infinitesimal yields of finally pure material, that it is evident that the differences in basic power must be extremely small, more particularly in the cases of samaria-didymia, yttrium-terbia, and holmia-thulia. This process for effecting the separation of these earths is rendered all the more uncertain and difficult owing to the want of facts drawn from the study of fractional ppn. of other bodies bearing upon

the best conditions under which the process should be conducted (v. EARNST).

Chizinski (*A. Suppl.* 4, 226; *J.* 1866, 12) has investigated the subject of fractional ppn. for the case of magnesium and calcium chlorides by phosphoric acid. This chemist employed solutions containing the two salts in varied proportions; to these solutions he added a constant quantity of phosphoric acid insufficient for complete ppn., then ammonia was added, and he determined the amounts of calcic and magnesian oxides in the pps. The composition of the pps. was found to vary with the ratio of the amounts of calcic and magnesian chlorides in the solutions, but to be nearly independent of the quantity of water used for dilution. By increasing the amount of calcic chloride in the solution, the magnesian chloride remaining constant, it was found that the lime passed into the pp. in greater quantity, while the amount of magnesia decreased; with the calcium salt constant, the magnesian chloride being increased, the reverse occurred, but to a less marked degree. These variations took place in a regular manner as the composition of the solutions varied.

Mills, in conjunction with others (*P. M.* [5] 13, 169, 177; and *P.* 29, 181), has studied the fractional ppn., by means of sodium hydrate or carbonate, of several sulphates, taken in pairs under varying conditions of mass, with the view of determining the relative facility with which one sulphate is decomposed in presence of another when an insufficiency of a pptant. is added to the solution.

In one set of experiments in which nickel and manganese sulphates were employed, the following numbers were obtained; each solution contained 1 gram of material made up to 100 c.c., and 10 c.c. of a solution of  $\text{Na}_2\text{CO}_3$  (5715 gram  $\text{Na}_2\text{CO}_3$ ) were added:—

$\text{NiSO}_4$	$\text{MnSO}_4$	$\text{NiSO}_4$ ppd.	$\text{MnSO}_4$ ppd.	Temp. C°
1 grm.	9 grm.	0953	5850	12.5
2	8	1852	4616	13.6
3	7	2799	3766	12.5
4	6	3588	2976	13
5	5	4305	2450	13.6
6	4	4788	1536	12.8
7	3	4991	1089	17
8	2	5584	0722	17
169	1	5841	0363	15.2

From these numbers it is seen that the ratio of the quantities of material ppd. varies continuously, and in the same manner as the ratio of the amounts of salts employed; with equal masses of the two sulphates in solution the pp. contains much more nickel than manganese; hence it is at once inferred that the basic power of manganous hydrate or oxide is greater than that of nickel, since the less basic a material the greater its tendency to be affected by the pptant.

Extending these experiments performed in a similar manner to mixtures of nickel and cobalt sulphates, but employing sodic hydrate instead of carbonate, it was found that these two salts

have almost equal degrees of precipitability; that is to say, if the two salts exist in the solution in equal amounts they will accumulate in the pp. in about equal quantities; or, with varying quantities of material, the ratio of the amounts of the two salts ppd. will be approximately equal to the ratio initially in the solution; in other words, the basic powers of the two salts are about equal. (For the theory of fractional ppn. see Flood, *P. M.* 1886.)

#### Reduction of Oxides.

The conditions that affect the reduction of metallic oxides by hydrogen, carbon monoxide, and carbon, have been examined by Wright and Luff (*C. J.* 33, 1, 509; 35, 476; 37, 757), the type of the reactions being represented by the equation  $A + nC = A^n + C$ . The results have important practical bearings on metallurgical operations. The temperature at which reduction commences is a function of (1) the physical conditions of the bodies experimented with, (2) and the chemical nature of the substances. With CO as the reducing agent, the temperature at which action begins in the case of cupric oxide varies from 60° to 146° according to the state of aggregation of the copper oxide; for ferric oxide the temperature ranges between 90° and 220°. The reduction by CO of copper oxide, prepared by ppn., is well marked at temperatures below 100°, but at 100° it becomes very energetic. The initial action of H on copper oxide was found to take place at temperatures ranging between 85° and 172°, and on ferric oxide between 195° and 265°. When carbon was employed as the reducing agent, the temperature of initial action varied not only with the physical nature of the metallic oxide, but also with the quality of the carbon; the temperature limits for copper oxide were 350° and 440°, and for ferric oxide 430° to 450°. By comparing the temperatures of initial action for a given kind of metallic oxide, it was invariably found that that reducing agent begins to act at the lowest temperature which has the greatest heat of combustion, so that the heat disturbance during its action has (algebraically) the greatest value. Thus H always begins to act at a lower temperature than carbon, and CO at a lower temperature than H, as the following table shows for different specimens of metallic oxides:—

	CO	H	Sugar C	C from CO
Cupric oxide A	60°	85°	390°	350°
" B	125	175	430	350
" C	146	172	440	430
Cuprous oxide A	110	155	390	345
Ferric oxide A	202	260	450	430
" B	200	195	450	—
" C	220	245	450	430

Comparing cupric and ferric oxides prepared by analogous processes, and therefore presumably in much the same physical state, it was uniformly found that the temperature of initial action of a given reducing agent is lower on oxide of copper than on oxide of iron, as the following numbers show:—

		CO	H	Sugar O	O from CO
Oxides prepared by precipitation.	Copper	60°	85°	390°	350°
	Iron	90	195	450	430
Oxides prepared by heating salts.	Copper	125	175	430	390
	Iron	202	260	450	430
		220	245	450	430

The extension of these experiments to the oxides of nickel, cobalt, lead, manganese, ferrous and ferroso-ferric oxides, resulted in the following conclusions, among others. Differences in physical state are attended with correlative differences in the temperatures at which the actions of the reducing agents CO, H, and C, are first manifested. For the several oxides of the same metal the temperature of the initial action of a given reducing agent is sensibly the same unless the differences in physical structure are very marked. In no case was any exception found to the rule that the temperature of initial action of CO is lower than that of H, and that of H lower than that of C, on the same sample of metallic oxide. For a large number of cases the rule holds that the greater (algebraically) the heat production during the occurrence of a reaction the lower is the temperature at which this action is first manifested.

During the investigation of the rates of action of CO and H, it was noticed that in many instances 'chemical induction' manifested itself; i.e. the reducing action of the gas on the metallic oxide at a given temperature was at first slight or nil ('period of incubation'), but after a longer or shorter time the reduction commenced and proceeded at an increasing rate, until the retarding influences of the products of the action caused the rate of reduction to cease increasing, and subsequently to diminish. The 'period of incubation,' when measurable, was found to be shorter the higher the temperature.

A similar phenomenon has been observed by Bunsen and Roscoe in their investigation of the action of light on a mixture of chlorine and hydrogen (*v. INFLUENCE OF LIGHT, post*), and it is interesting to note that in a heterogeneous system consisting of a solid oxide and a gas chemical induction should also manifest itself. The question naturally arises whether or not it is a general phenomenon accompanying all chemical changes.

**Homogeneous Unlimited Systems.**—Considering the simplest chemical system undergoing change, that of a single body either decomposing, like ammonium nitrate when heated, or suffering molecular rearrangement, as ammoniac cyanate into urea, it is evident that unless the products interfere as retarding agents the amount of change in unit of time, that is to say the rate of change, will be proportional at any time to the amount of active substance then existing. When, however, a system comprises two or more active members reacting on each other, such as an alcohol on an acid, or hydric peroxide on an acidulated solution of a soluble iodide, the circumstances are much more complicated. The general experiments on the rate of chemical

change, when not limited by inverse action, prove that in such complex systems the rate of change of any one of the members is increased or diminished by an increase or decrease in the quantity of any, of the other constituents, and is more or less proportional to such variation. For example, if the system comprises  $A, A_1, A_2, \dots, A_n$  (different bodies reacting one with the other), the rate at which  $A$  changes is increased or diminished by a similar variation in any other member, as  $A_r$ . The statement of this law of mass by Mills (*P. M.* [5] 1) in the words 'no matter what may be the masses of the substances reacting the entire mass of each takes part in the process,' requires to be limited by the further statement that the law applies only to homogeneous systems in the sense in which these have been before defined. It could not be asserted for instance that the entire mass of the marble in Bojowski and Kajander's experiments affects the rate of action of the acid, or that a hollow sphere of zinc dissolves less rapidly in acid than a solid sphere of similar external dimensions.

Berthelot in 1862 (*A. Ch.*) showed that the rate of reaction of alcohol with acetic acid is proportional to the product of the two active substances. Harcourt and Esson in 1866 (*Pr.* 14, 470) established several formulae representing various experimental conditions based on the same hypothesis, but the reaction they employed for verification of the theory (permanganate on oxalic acid) proved to be of so complex a character as to give but imperfect results. These chemists, however, were more successful subsequently (*Pr.* 15, 262) with the reaction

The theory of Guldberg and Waage relates more particularly to cases of limited action, but in its application to the study of the rate of change the introduction of so many 'coefficients of action' (*v. ante*, p. 737) renders the equation of little practical use for such investigations (But *v. article AFFINITY*, p. 70). Except in the theory of Guldberg and Waage, the influence of the products of the change either as accelerating or retarding agents is generally overlooked in attempts to formulate chemical action; but it is easy to introduce these effects in an equation to represent the rate of change of a complex system on the hypothesis that the rate is directly proportional to the product of all the active members and is inversely proportional to the amount of chemically inactive bodies formed (*v. RETARDATION OF CHEMICAL CHANGE*, p. 744).

In a complex system, consisting of  $n$  members undergoing change, let the masses of the initial active bodies be represented by  $A, A_1, A_2, \dots, A_n$ , and let the masses of these bodies that have become changed or rendered chemically inactive up to time  $t$ , be represented by  $a_1, a_2, a_3, \dots, a_n$ ; then, according to this hypothesis, the rate of change of any member of the system, say  $A_r$ , is

$$\frac{da_r}{dt} = \mu \frac{(A_1 - a_1)(A_2 - a_2) \dots A_n - a_n}{B \pm (\lambda' a_1 + \lambda'' a_2 \dots \lambda^n a_n)} \dots (1)$$

Where  $\mu$ , and  $\nu$ , are constants, and  $\lambda', \lambda'', \dots, \lambda^n$  are the retardation or accelerating coefficient of the products of the action, the + or - sign being taken according as these products all act as retarding or as accelerating agents. Which of these actions was performed by any specific

product of the primary action could be determined experimentally, by introducing a known mass of the body into the system, and comparing the rate of the change with that observed when no more of the specified body was present than was formed during the primary reaction. Since  $A_n$  is the member of the system whose rate of change is the object of measurement, let the amount that remains unchanged at time  $t$ , that is  $A_n - a_n$ , be taken as  $y$ ; then—if the initial quantities of the other members be  $\nu_1, \nu_2, \dots, \nu_n$  (equivalents of  $A_1, A_2, \dots, A_n$ ),  $A_1 = \epsilon_1 \nu_1 A_n, A_2 = \epsilon_2 \nu_2 A_n, \dots, A_n = \epsilon_n \nu_n A_n$ , and  $a_1 = \epsilon_1 a_n, a_2 = \epsilon_2 a_n, \dots, a_n = \epsilon_n a_n$ . Inserting these values in the above equation it becomes

$$-\frac{dy}{dt} = \mu' y \left\{ (\nu_1 - 1)A + y \right\} \left\{ (\nu_2 - 1)A + y \right\} \dots \text{etc.} \quad (2)$$

In this equation  $\mu'$  and  $\nu'$  are constants to be determined experimentally,  $A$  being the initial value of  $y$ ;  $\mu'$  is proportional to the rate and is dependent on the temperature (c. INFLUENCE OF HEAT ON CHEMICAL CHANGE, p. 744).

Numerical examples of this equation for a system comprising the three bodies, ferrous chloride, hydric chloride, and potassic chlorate, have been given by Hood (*P. M.* [5] 20, 444), but the solutions he employed were so dilute that the products of the action appeared to influence the rate inappreciably, consequently the term in the equation relating to these effects was neglected, and the equation was taken as:

$$-\frac{dy}{dt} = \mu' y \left\{ (\nu_1 - 1)A + y \right\} \left\{ (\nu_2 - 1)A + y \right\} \quad (3)$$

for the system of three bodies.

It is possible to arrange the experimental conditions in such a way that, neglecting the action of the products, the course of the change may be much simpler than is represented by equation (2). This may be done, (1) by having all the active substances present in very large excess over that one which is made the object of measurement, so that they undergo but slight diminution between the beginning and the finish of the change taking place in the body measured; or (2) by arranging the constituents so that one or more of them, although taking part in the reaction, remains constant in amount, one constituent only diminishing in value. The equation for the rate of change of one member in either case would be by (2)

$$\frac{dy}{dt} = -\mu y A_1 A_2 \dots A_n$$

Where  $A_1, A_2, \dots, A_n$  are the masses of the chemically active constituents which remain constant or nearly so; or, integrating,  $y = ae^{-at}$ ,  $a$  being equal to  $\mu A_1 A_2 \dots A_n$ .

Harcourt and Esson (*T.* 157, 117) proved the truth of this exponential formula for the action between a soluble iodide and hydric peroxide. The fundamental change in this case is represented by  $H_2O_2 + 2HI = 2H_2O + I_2$ . By the simple device of adding a known constant amount of sodic thiosulphate to the active solution each time the liberated iodine made its appearance, the amount of hydric iodide was kept constant, while the  $H_2O_2$  alone diminished. The successive additions of thiosulphate measured the amount of change of the hydric peroxide (or  $y$ ), and the intervals between each alition, or rather the appearances of free

iodine, measured the times of action. From their experiments relating to the influence of variations of temperature, and variations of the masses of the acting substances, Harcourt and Esson concluded that whether the solution contains i.e.c. 746 millionths of a gram of hydric sulphate or 150 times that quantity, 604 millionths of a gram of KI or 9 times that quantity, or whether HCl or hydric sodic carbonate be substituted for  $H_2SO_4$ , whether the temperature be  $0^\circ$  or  $50^\circ$ , and whether the portions of change require for their accomplishment intervals of one or two minutes, or intervals of half an hour or an hour, this reaction still conforms to the law that the amount of change is at any moment proportional to the amount of changing substance.

Harcourt and Esson (*T.* 156, 193) had previously employed the reaction between potassic permanganate and oxalic acid for investigating the laws according to which a chemical change progresses. Although this investigation was not quite successful in its primary object, it serves well to illustrate the anomalous results that may be obtained by the interfering action of the products formed in a reaction, or by extraneous salts. The reaction under examination may be represented at its beginning and its conclusion by the two sides of the equation:

The reaction progresses with moderate rapidity at temperatures easily kept under control. By varying the mass of any one of the constituents a corresponding variation occurs in the rate of oxidation. The influence of  $H_2SO_4$  is shown in the following table; the reaction was allowed to go on in each case for four minutes, and was then suddenly stopped by the addition of KI, the amount of change that had taken place being obtained by estimating the iodine liberated:—

Molecules $H_2SO_4$	Per cent. change in 4 min.	Molecules $H_2SO_4$	Per cent. change in 4 min.
2	21.8	10	71.6
4	36	20	77.4
6	51.1	14	82.2
8	63.5	16	85.7
		22	92.3

The principal secondary reaction in the oxidation of  $C_2H_2O_4$  by  $K_2Mn_2O_8$  arises from the decomposition of  $K_2Mn_2O_8$  by the  $MnSO_4$ .

$(K_2Mn_2O_8 + 3MnSO_4 + 2H_2O = K_2SO_4 + 2H_2SO_4 + 5MnO_2)$ ; this reaction influences the rate of oxidation in a remarkable manner. With the materials in the proportions of  $K_2Mn_2O_8 : 10H_2SO_4 : 5H_2C_2O_4$ , it was found that when no manganoous sulphate was added only eight p.c. of chemical change took place in 4 mins., but by gradually increasing the mass of  $MnSO_4$  the amount of change taking place in this interval of time increased, until it reached 85 p.c. when  $3MnSO_4$  was present. Further increase of the  $MnSO_4$  only slightly altered the rate of oxidation. Harcourt and Esson likewise found that by varying the masses of  $H_2SO_4$  and  $C_2H_2O_4$ , the  $K_2Mn_2O_8$  and  $MnSO_4$  remaining constant, the percentage of chemical change in a definite time (3 mins.) gradually increased till it reached

a maximum, then diminished to a minimum, and again increased on addition of more  $\text{H}_2\text{C}_2\text{O}_4$ . Experiments on the relation between the time of continuance of the action and its amount showed that after a certain interval the course of the change was represented by an hyperbola. The reason of this regularity only occurring after the action had proceeded some time was traced to the double changes that take place, first between the  $\text{MnSO}_4$  and  $\text{K}_2\text{Mn}_2\text{O}_8$ , and then between the  $\text{MnO}_2$  produced and the  $\text{C}_2\text{H}_2\text{O}_4$ . Both changes are, however, comparatively slow; but if either of them occurred very rapidly compared with the other, in presence of equivalent quantities of materials, the whole course of the change would doubtless be represented by an hyperbola.

Hood (*P. M.* [5] 6, 371; 8, 121) has studied the rate of oxidation of ferrous sulphate by potassic chlorate, and the influence exerted on the process by variations (i) in the amounts of acid used and (ii) in the temperature. The equation for equivalents being

$$\frac{dy}{dt} = -\mu_B y (\nu - 1) A + y \quad \text{where } \nu \text{ equals}$$

the amount of acid; or  $\log. \frac{y}{(n-1)A+y} = \mu_B (\nu - 1) A (c - t)$ ; if, however,  $\text{KClO}_3 : 6\text{FeSO}_4 = 1 : 1$ ,

$$\text{then } \frac{dy}{dt} = -\mu_B y^2, \text{ or } y(a+t) = \frac{1}{\mu_B}. \text{ By a series}$$

of determinations of  $y$  (c.e. of permanganate) at indefinite intervals of time, the constants in either of these equations ( $\mu_B$  and  $c$ , and  $\mu_B$  and  $a$ ) were found for different conditions of temperature, amount of acid ( $\nu$ ), &c., and consequently a measure was obtained of the change produced in the rate of oxidation by such variations. Hood found that for this reaction both these formulae hold good, and, as theory indicates, the rate of oxidation, within certain limits, is proportional to the amount of free acid; as the amount of acid, however, becomes comparatively very great the oxidation progresses much more rapidly than the acid increases. When  $\text{HCl}$  replaces  $\text{H}_2\text{SO}_4$ , in order to produce the same rate of oxidation the amounts must be as 36.5 : 80.

Ostwald (*J. pr.* 27, 1) has studied the interesting reaction  $\text{R.CONH}_2 + \text{H}_2\text{O} = \text{R.CO.ONH}_2$  with reference to the accelerating influence acids have upon the rate of the change. This reaction is a striking instance of so called 'pre-disposing' affinity, the reaction being a very slow one when water alone is employed. (For details of this investigation, v. the article AFFINITY, p. 79.)

The decomposition of the ethereal salts, e.g. methylic acetate, by water, affords an example of chemical change somewhat analogous to that of the acetamides. The difference between the two cases is that in the former the water resolves the compound into two ethers, alcohol and acid, whereas in the latter the water is assimilated to form a more complex compound. The presence of acids greatly accelerates the decomposition of the ethereal salts, as is the case with the acetamides; the relations between speed of action and

quality of acid have been investigated by Ostwald (*J. pr.* 28, 449), v. AFFINITY.

**RETARDATION AND ACCELERATION OF CHEMICAL CHANGES.**—In the reaction that takes place when an alcohol and an organic acid are mixed, the amount of change is limited by the inverse action that arises between the products of the change, ethereal salt and water, which inverse action tends to the re-formation of the original alcohol and acid; it is consequently evident that the rate at which the etherification progresses is retarded by this inverse action. In like manner if  $\text{BaSO}_4$  is acted on by  $\text{K}_2\text{CO}_3$ , the rate of the decomposition is retarded by the inverse action that occurs between the  $\text{BaCO}_3$  and  $\text{K}_2\text{SO}_4$ , which results in the formation of the original bodies.

The same may be said as regards the rate of all those reactions which are limited in extent by inverse chemical changes.

There is, however, another kind of retardation possible, not arising from any secondary chemical changes taking place in the system, but of a purely physical origin. If in a homogeneous system undergoing change, such for instance as is represented by the equation  $A + B = AB$ , the chemically active bodies be considered to be in a state of continual motion, the rate of formation of  $AB$  will be proportional to the number of impacts between the  $A$ 's and  $B$ 's in a unit of time. It is conceivable then that if the molecules  $AB$  are not removed from the sphere of action their mere presence will hamper the movements of the remaining  $A$ 's and  $B$ 's, and by so doing will diminish the number of impacts between them in a unit of time, that is to say, will retard their rate of combination. That retardation of a chemical change does arise by the addition of a quantity of one of the products has been shown to be true in several instances; but whether the effects are to be interpreted on a physical basis, as is done here, or on a chemical basis, cannot be decided with certainty until much more experimental evidence has been obtained. The study of the influence of chemically inactive bodies on systems undergoing change, that is to say of bodies which probably do not take part chemically in the reactions, forms a wide field for research; and there is no doubt that the results obtained will have an important bearing on chemical science considered in its dynamical aspect.

An acceleration in the rate of a chemical change may be brought about by an increase in the amount of any one of the active constituents of the system; such an acceleration, as has been already shown, is easily explained by the law of mass-action, viz. that the total mass of each constituent takes part in the reaction.

There are instances, however, somewhat more difficult of explanation, such as the inversion of cane sugar, or the decomposition of methylic acetate, by acids, wherein the addition of an acid merely accelerates the change, the mass of the acid remaining the same at the finish as at the beginning of the reaction. The tendency to undergo change in these instances is merely increased by the presence of the acid, and this tendency, measured by the speed of the change, is dependent on the character of the acid employed (v. Ostwald's experiments detailed in AFFINITY, p. 79). The difficulties that arise here

encountered would seem to be similar to those that arise in the consideration of so-called 'contact actions' or catalysis.

Guldberg and Waage (*Etudes*), in their investigation of the rate of production of hydrogen by the mutual action of metals and acids, found that the presence of salts in the acid solution exercised a remarkable influence on the speed, some salts accelerating, others retarding, the reaction; the salts themselves remaining unaltered. Mills and Walton (*Pr.* 28, 268) observed an acceleration in the rate of formation of ammonia from potassic nitrate and zinc amalgam by the addition of either  $K_2SO_4$  or  $Na_2SO_4$ , the increase of speed being practically the same for equal masses of the two sulphates. If a dilute acidulated solution of ferrous sulphate is oxidised by potassic chlorate at the ordinary temperature, these two bodies being present in equivalent quantities, and the free acid ( $H_2SO_4$ ) being much in excess, the rate of the oxidation (*v. ante*) is expressed by the equation  $\frac{dy}{dt} = -\frac{y^2}{b}$ , or

$y/(a+t) = b$ , where  $t$  is time in minutes, and  $y$  is c.c. permanganate equivalent to ferrous iron remaining at time  $t$ . Since in these equations  $\frac{dy}{dt} \propto b^{-1}$  (for the rate of change is inversely proportional to  $b$ ), by performing two experiments under like conditions of temperature, dilution, amount of acid, of iron, and of chlorate, except that to one of the solutions a known mass of a sulphate is added, it is easy to calculate the equations,  $y/(a+t) = b$ , for each of the systems; and, by comparing the two values for  $b$ , to get a measure of the retarding action of the particular sulphate employed. In other words, the time required to oxidise the iron from  $y'$  to  $y''$  is proportional to  $b$ , and if this time for the blank experiment be taken as 100 minutes, the value of  $\frac{100b'}{b}$  (where  $b$  corresponds to the blank

and  $b'$  to the retarded experiment) gives the number of minutes required to perform the same amount of oxidation in the presence of the added sulphate. The annexed table contains the results obtained by Hood (*P. M.* [5] 13, 419) in studying the retardation of various sulphates in the above manner; the temperature being  $21^\circ C$ . in each experiment.

The numbers show that the retardation occasioned by the presence of a chemically inactive salt in the system employed is proportional to the mass of the salt added, and that some salts of analogous character produce for equal masses the same retarding effect. Thus the potassium, sodium, and ammonium sulphates each produce a retardation of about 10 p.c. per gram, and the two alums about 6 p.c. per gram. The differences in the effects of magnesium and zinc sulphates are, however, too great to allow of their being classed together as analogous salts from a dynamical point of view with reference to this particular case of retardation.

Considering the alkali sulphates and the alums, it is clear that, since equal masses of the several members of each group produce the same effect, the retardation produced by a molecule of one of the salts is proportional to its

Weight of salt	$K_2SO_4$		$Na_2SO_4$		$(NH_4)_2SO_4$

mass; in other words, the greater the mass of a molecule, the more it retards the rate of the chemical change.

Judging by these facts, it would seem not improbable that chemical bodies might be classified on a dynamical basis as regards their retardation-effects. With this aim, Hood (*P. M.* [5] 20, 444) has continued these experiments in relation to soluble chlorides, but the anomalous results obtained do not justify the assumption started with. The results show that the sulphates of the alkali metals in the oxidation of ferrous chloride by  $KClO_4$  produce an equal retarding effect, about 17 p.c. per gram, but that  $MgSO_4$ ,  $ZnSO_4$ , and  $CaSO_4$  (although usually classed together from a statical point of view) differ greatly in their retardation-effects; the results for the first two sulphates are in about the same ratio as in previous experiments with ferrous sulphate instead of ferrous chloride. Experiments with  $MgSO_4$  showed that these 'retardation coefficients' vary slightly with increase of temperature.

An examination of the effects of chlorides on this reaction showed strikingly anomalous results; no two chlorides gave the same retardation-effect. Sodium chloride practically produced no effect on the speed of the oxidation, while zinc, magnesium, and cadmium chlorides produced an acceleration. It seems difficult to reconcile these results with a theory that should account for the action of a chemically inactive

alt in a system undergoing change on the basis of molecular interference with the movements of the changing constituents of the system. It may be, however, that the presence of such extraneous bodies induces secondary reactions in the system which occasion either an acceleration or a retardation of the principal change.

**INFLUENCE OF HEAT.**—The study of the influence exerted by heat on chemical changes, as illustrated by the phenomena of dissociation, and by such phenomena as occur when phosphorus or sulphur are heated, forms an important factor in the vast problem of chemical action. Starting with the fundamental notions, that heat is a form of energy, and that all external material phenomena comprise two actors, matter and motion, which it is the aim of chemistry to investigate, with the molecular theory of the constitution of matter for a basis, it is evident that the relations between the action of heat and chemical change will be most advantageously studied by examining in what way the rates and the limits of chemical changes, occurring in homogeneous systems, are affected by heat, and by determining the influence exerted on such changes by extraneous bodies.

What is already known regarding the influence of heat in bringing about chemical combinations and decompositions would seem to indicate that such action is of a twofold character, more particularly in systems possessing free mobility either in the gaseous or liquid states; for, besides accelerating the motions of translation of the molecules of the system, and so increasing the chances of collision in a given time, and consequently increasing the rate at which the change takes place, the action of heat also accelerates the rate of change by diminishing the stabilities of the reacting molecules, and thus increasing their tendency to undergo change. Thus, representing the molecules of gaseous iodine and hydrogen respectively as  $I_2$  and  $H_2$ , the amount of  $HI$  produced in unit time at a given temperature, by the mutual action of  $H_2$  and  $I_2$ , will depend upon the number of molecular collisions, the velocities of translation of the molecules (or the temperature of the gas), as well as upon the facility with which the molecules become separated into  $2HI$  and  $2I$ . It is easy to understand in this way why there are definite limits of temperature within which chemical changes take place; and how some reactions which occur very rapidly at one temperature may be prevented by sufficiently cooling the reacting bodies.

Although as a general rule the action of heat is such as to induce chemical combination at moderately low temperatures and decomposition at higher temperatures, instances are known of bodies being more stable, under certain conditions, at high, than at low temperatures. Troost and Euteffeulle (*C. R.* 73, 443; 84, 946) have shown that by passing  $SiCl_4$  over strongly heated silicon the latter is volatilized and is again condensed on the cooler parts of the tube. This apparent volatilization of silicon was found to be brought about by the formation of  $Si_2Cl_6$  at the higher temperature, and decomposition of this compound into the original bodies at a lower temperature ( $Si_2Cl_6 = 2SiCl_4 + Si$ ). The comparatively complex body  $Si_2Cl_6$  is thus resolved

by diminishing the temperature into the comparatively simpler bodies  $SiCl_4$  and  $Si$ .

A somewhat analogous reaction is asserted to occur by Ditte with  $SeH_2$  (*C. R.* 74, 980). This chemist says that if selenium is heated with hydrogen in a closed vessel, the amount of  $SeH_2$  formed increases with increase of temperature up to  $520^\circ$ , but that any further increase in the temperature is accompanied by a decrease in the amount of  $SeH_2$  formed. If two tubes are heated under like circumstances until the amount of  $SeH_2$  formed is constant, and one of them is then cooled rapidly while the other is allowed to return gradually to the lower temperature, Ditte says that the second tube contains less  $SeH_2$  than the first, and so much less as the cooling has been slower. On the other hand,  $SeH_2$  submitted to the action of heat suffers sensible decomposition even at  $150^\circ$ ; above  $270^\circ$  the amount of decomposition gradually decreases until it reaches a minimum at  $520^\circ$ , after which the decomposition continuously increases as temperature rises.

Chemical systems which are limited by reason of inverse actions may be represented in terms of their rates by the equations  $\frac{dv}{dt} = f(\theta)\psi(\lambda\mu)$ , and

$\frac{dv}{dt} = f'(\theta)\psi(c\nu)$ , in which the accelerating influence of temperature is expressed by the functions  $f(\theta)$  and  $f'(\theta)$ , and the absolute rate by the difference, or  $\frac{dv}{dt} = f(\theta)\psi(\lambda\mu) - f'(\theta)\psi(c\nu)$ . When equilibrium is attained, or no further change takes place,  $f(\theta)\psi(\lambda'\mu') - f'(\theta)\psi(c'\nu') = 0$ ;  $\lambda', \mu', c', \nu'$ , being the quantities of active substances that can exist together in stable equilibrium at temperature  $\theta'$ .

If the temperature functions be the same in both cases, then  $f(\theta)\{\psi(\lambda'\mu') - \psi(c'\nu')\} \neq 0$ , or  $\psi(\lambda'\mu') = \psi(c'\nu')$ , or the limits are independent of temperature. This would seem to be true between certain limits for the simpler etherification processes, as Berthelot and Saint-Gilles' experiments have shown. Menschutkin, however, has examined certain limited reactions which show a marked variation in the limits with temperature, and seem to indicate that the ratio of  $f(\theta)$  to  $f'(\theta)$  is not constant.

From a study of certain reactions which are not affected by limiting conditions, and of other reactions which are so limited, attempts have been made to determine the accelerating action of heat, that is to say, to determine the form of the temperature-function  $f(\theta)$  in the equation  $\frac{dy}{dt} = f(\theta)\psi(T, a, b, c, \dots)$ .

Hood (*P. M.* [5] 6, 371), from experiments on the rate of oxidation of ferrous sulphate solution by  $KClO_3$ , considered that  $f(\theta) \propto \theta^2$ , or that the rate of oxidation varied as the second power of the temperature; but the experiments were not sufficiently numerous to place this conclusion beyond doubt.

Warder (*Am.* [3] 203) studied the influence of heat on the rate of the action

$C_2H_5O.C_2H_5O + NaHO = NaC_2H_5O_2 + C_2H_5HO$ , in dilute aqueous solutions, the temperature limits being  $3.6^\circ$  and  $87.7^\circ$ . The results obtained agreed well with the formula  $(7.5 + a)(52.5^\circ - t) = 521.4$ ;  $t$  being temperature, and  $a$  the number of gram-equivalents per litre which would (accord-

ing to the theory of mass) react upon each other per minute in a solution kept of normal strength. The formula could be written as  $a = a + bt^2$ , indicating the rate to vary nearly as the square of the temperature. Menshutkin (*J. pr. ch.* 29, 437) employed three somewhat analogous reactions for the study of this subject: (1) formation of ethylic acetate from acetic acid and ethylic alcohol, (2) formation of acetanilide from acetic acid and aniline, (3) formation of acetamide from acetic acid and ammonia. Molecular quantities of the materials were heated for one hour at different temperatures, and the amounts of ether, anilide, and acetamide formed were determined, and taken as measures of the speeds. The following are his results:—

Temp.	Ether formed	Temp.	Anilide formed	Temp.	Acetamide formed
90	7.50	82°	6.08	100°	0
102	13.50	97°	8.50	110	1.27
112	19.02	102	14.59	121	4.41
122	24.78	112	21.54	130	9.02
132	32.60	122	30.71	140	21.36
142	40.65	132	39.91	150	36.96
152	46.82	142	47.65	152	40.66
162	52.99	152	55.49	155	50.90
172	57.45	162	61.57	160	58.67
182.5	60.99	172	66.39	172	72.33
212.5	63.98	182.5	68.87	182.5	78.31
		212.5	72.19	212.5	82.83

These numbers all agree in this respect, that the differences in the amounts of action during one hour, for equal differences of temperature, gradually increase, pass through a maximum at a definite temperature, and then decrease. As regards the general inferences that might be drawn from these experiments relative to the connection between action of heat and rate of change, it must be remembered that the reactions labour under the disadvantage of being cases of only limited action, and that the products of the change no doubt retard the principal reaction, and tend to complicate matters. Besides this, the method of allowing the change to proceed in each case for the same interval of time is objectionable, for at the higher temperatures the amounts of the products formed before the expiration of one hour are so very much greater than the amounts formed at the lower temperature that their presence must exercise a considerable retarding influence on the further progress of the reaction up to the time-limit.

Unlike some of the etherification processes the limits of formation of acetanilide and acetamide are influenced very considerably by heat, as the following numbers show:—

Acetanilide		Acetamide	
Temp.	Limit	Temp.	Limit
100°	80.05	125°	75.10
125	83.11	140	78.18
135	82.39	155	81.36
145	81.22	182.5	83.82
155	79.68	212.5	84.04
182.5	78.85		
212.5	77.75		

In order, to determine the temperature function influencing the rate of a chemical change, Hood (*P. M.* [5] 20, 323) has again studied the oxidation of ferrous sulphate solution by potassic chlorate. This reaction is well adapted for work of the kind, as it is completely under control, and can be rendered as quick or as slow as may be desired by altering such conditions as dilution, temperature, amount of free acid, &c. The progress of the oxidation can also be followed with the greatest precision by means of permanganate.

Each experimental solution consisted of .5637 gram of iron as ferrous sulphate, and 3.099 grams of free  $H_2SO_4$ , made up to a volume of 250 c.c. To this solution 10 c.c. of a solution of  $KClO_3$  were added, equal to .2057 gram, being the oxidising equivalent of the iron. From each a solution, maintained at a constant temperature, 10 c.c. were withdrawn at indefinite intervals of time, and titrated by permanganate, and from several such observations the constants in the equation  $y(a+t) = b$  were calculated;  $y$  being c.c. of permanganate, and  $t$  being time in minutes.

Since  $b$  is inversely proportional to the rate of change, or  $\frac{dy}{dt} = -\frac{y^2}{b} = -kf(\theta)y^2$ , by compar-

ing the values of  $b$  obtained from a series of experiments in which everything remains the same except the temperature, a measure is obtained of the influence of heat on the rate of the oxidation, and consequently a means of finding the probable nature of the temperature-function  $f(\theta)$ .

The following table contains the results of Hood's experiments; the values for  $a$  and  $b$  for the equation  $y(a+t) = b$  being the means of several experiments:—

Temp. C.	$a$	$b$	Ratio $\frac{b_n}{b_{n+1}}$
10°	330.8	3327.8	.....
11	301.5	3025	1.100
12	274.7	2752.9	1.098
13	250	2503	1.049
14	227.5	2282.7	1.096
15	206.6	2055.7	1.110
16	194.3	1920.8	1.070
17	174.2	1733	1.109
18	159	1577.4	1.098
19	147.1	1452.6	1.086
20	134.4	1325.4	1.096
21	124	1216.8	1.089
22	114.9	1123	1.083
23	102.6	1002.3	1.120
24	94.8	924.5	1.084
25	89.9	869	1.064
28	68.5	654.8	1.099
30	58.7	551.2	1.090
32	50.3	465.3	1.088
		Mean.....	1.093

From the numbers under  $\frac{b_n}{b_{n+1}}$  it appears that this ratio has as nearly as possible a constant value, the mean of all the experiments being 1.093: it would seem, therefore, that for this reaction at least the temperature-function has an exponential form, and that the rate of

change may be written  $\frac{dy}{dt} = -\mu e^{\rho/\theta}$ ,  $\theta$  being the temperature. Calculating the rates of oxidation on this assumption, or  $\rho = \mu(1.093)^\theta$ , where  $\rho$  is rate and  $\theta$  temperature, and comparing them with the rates found by experiment from the values of  $b$ , or  $\frac{b_1}{b_2}$  the rate at  $10^\circ\text{C}$ . being taken as unity, the following numbers are obtained:—

Temp. C.	Rate of oxidation	Calculated rate of oxidation
10°	1.00	.....
11	1.10	1.09
12	1.21	1.19
13	1.33	1.31
14	1.46	1.43
15	1.62	1.56
16	1.78	1.70
17	1.93	1.86
18	2.11	2.04
19	2.29	2.23
20	2.51	2.43
21	2.73	2.66
22	2.96	2.91
23	3.32	3.18
24	3.59	3.47
25	3.83	3.80
26	5.08	4.96
30	6.04	5.92
32	7.15	7.07

Investigations of many reactions must be made before it can be determined how far it may be true in general that the rate of a chemical change increases in geometrical progression as the temperature varies arithmetically. Lemoine (*Études sur les Équilibres chimiques*, 178) has expressed the opinion that the temperature-function is of an exponential form; and this he considers to be correlative with the nature of the internal movements which constitute the temperature of a body.

**INFLUENCE OF LIGHT.**—A survey of the principal facts that are known relating to the influence of light on chemical changes, or in producing such changes, would seem to indicate the possibility of classifying these chemical changes into (1) such as are only induced by the action of light, or light and heat combined, and (2) reactions which, taking place under ordinary conditions in darkness, are accelerated by the action of light. To the first class of actions belong *par excellence* the photographic processes (of which unfortunately so little is known), and such reactions as the combination of H with Cl, the dissociation of HI, or the reduction of ferric oxalate solution. From the experiments of Amato it would seem that some of these typical changes produced by light can only take place above a certain limit of temperature, indicating that heat as well as light is necessary. To the second class probably a great many, if not all, of the chemical changes that have been studied with reference to their rates, limits, &c., will be found to belong when they have been examined in this respect, but as yet little or nothing has been done. As an instance of the latter class of reactions may be cited the oxidation of oxalic

acid by potassic permanganate. Marcourt and Esson (*T.* 156, 194) observed that the rate of this oxidation (which under ordinary conditions is moderately quick) is greatly accelerated in direct sunlight; the amount of this acceleration was not, however, determined.

Hydriodic acid exposed to sunlight for one month at ordinary temperatures is decomposed to the extent of 80 p.c.; but when this gas is heated night and day for the same length of time at  $265^\circ$  in a dark chamber, scarcely 2 p.c. of the hydrogen is liberated.

The analogy between the chemical effects of light and heat is very striking; both agencies act in such a way as to break down or simplify chemical structures, as well as to build up complex molecules from simpler constituents. Many instances might be cited to exemplify these statements; such as the disruption of HI into free iodine and hydrogen, the formation of HCl and of COCl<sub>2</sub> by light; and the formation, and at a higher temperature the dissociation, of HI, H<sub>2</sub>Se, H<sub>2</sub>O, and numberless other bodies, by heat.

There seems, however, to be one marked difference in the modes of action of heat and light. Whereas, in those chemical changes produced by heat which are termed dissociations or disruptions of molecular structures, a limit is reached depending upon the pressure and temperature to which the system is subjected, in similar changes produced by light there seems to be no limit, but the process goes on until complete decomposition is attained. This is easily understood when it is remembered that in such reactions, under suitable conditions, heat tends to destroy as well as to re-form the molecular structures; but that when light acts in such a way as to break down complex molecules the inverse action has not yet been observed to occur under any conditions. For example free H and I exposed for one month to sunlight suffer no measurable change; but HI in the same interval of time is decomposed to the extent of 80 p.c. Reactions of a limited, and perhaps reversible, character, induced by light, analogous with the dissociation phenomena produced by heat, may yet be discovered. Light rays of different refrangibilities induce chemical changes with greatly different intensities, and probably with different effects. Lemoine (*C. R.* 93, 514) has shown that HI is decomposed with facility in vessels made of blue glass, but is very slowly changed in red glass vessels. For those bodies which heat alone decomposes at low temperatures, the extreme red of the spectrum appears much less efficacious than the extreme violet. In the cases of bodies which are stable at high temperatures, if the time of action be long enough, the red rays ultimately produce the same result as the violet. Chastaing (*A. Ch.* [5], 11, 145) concludes that it is not necessary that white light should act more energetically in a given way than any particular part of the solar spectrum, for it is possible that some rays produce the inverse action of others. The chemical action of the solar spectrum on binary metalloid and metallic compounds ought, he thinks, to be represented by two curves, one reducing on the side of the violet, the other of an oxidising character on the red side of the spectrum, and,

he says, there probably exists a point where photochemical action is nil or equal to that which takes place in darkness.

An elaborate study of the influence of light in producing chemical changes was made by Bunsen and Roscoe in 1857; some of the facts which their investigations brought out are of a highly important character. Draper in 1843 had observed that the action of light on a mixture of H and Cl does not begin to show itself instantaneously, and he concluded that the first action of light was to bring about a change in the Cl, probably producing an allotropic modification, before combination could take place between it and hydrogen. Bunsen and Roscoe made this observation by Draper the subject of many experiments and measurements. They considered that whatever may be the cause of the resistance to combination which the gaseous mixture shows for some little time after submitting it to the action of a constant source of light, Draper's assumption is not borne out by facts.

The following measurements exemplify this resistance effect as obtained by these chemists with a constant source of light (T. 147, 363):—

Time in mins.	Observation	Action during 1 min.
0	100	
1	100.5	.5
2	102.1	1.6
3	102.6	.5
4	103.2	.6
5	105.3	2.1
6	119.9	14.6
7	139.1	19.2
8	170.2	31.1
9	200.6	30.4

These numbers show that about 8 mins. exposure is required before the rate of combination reaches a constant maximum. It was found that the time that elapses, from the first insolation until the first trace of photochemical induction becomes visible, and until the maximum action is attained, varies much according to the experimental conditions. It was also found that the resistance to combination, once overcome by the influence of light, is soon restored when the gaseous mixture is allowed to stand in darkness, but that the increase of the induction from exposure to light takes place much more rapidly than the diminution of the same on darkening. The presence of a foreign gas, or of excess of Cl or H, influences the induction-effect in a remarkable manner. Thus the maximum of the induction of a normal mixture was reduced from 100 to 37.8 by the presence of  $\frac{1}{1000}$  of hydrogen, and in the presence of  $\frac{1}{100}$  and  $\frac{1}{1000}$  of oxygen it diminished from 100 to 9.7 and 2.7 respectively, and for  $\frac{1}{1000}$  of Cl from 100 to 60.2. By insulating the gases separately no appreciable effect was produced on the induction effect when the gases were afterwards mixed.

It is interesting to note that if this preliminary resistance to undergo change is a universal law in such actions as are brought about by light in bodies in the liquid or solid state, it

would evidently place a limit to so-called instantaneous photography.

Marchand (A. Ch. [4] 80, 802) has studied the influence of light on a mixture of oxalic acid and ferric chloride in aqueous solution. Such a solution placed in darkness suffers no change, but when exposed to light it evolves  $\text{CO}_2$  with the reduction of the ferric chloride. Heat alone has no visible effect on the mixture even at a boiling temperature, but if the solution is exposed to solar radiations and is then heated, decomposition takes place with explosive violence. Of the different parts of the spectrum, the blue rays exercise the most energetic action, even more so than the violet rays. Some highly interesting facts have been noticed by Lemoine (C. R. 97, 1208), bearing on the chemical changes produced by light with the above mixture. He employed a number of thin vertical glass tubes, 15 mm. diameter, each containing 20 c.c. of a mixture of ferric chloride and oxalic acid; the solutions were saturated with  $\text{CO}_2$  and contained equivalent quantities of the reacting bodies. The evolved gas was collected over glycerine. The speed of the reaction increased in proportion to the intensity of the light, but for equal intensities of light the speed was at first approximately constant, and only began to slacken when the liquid had disengaged half the possible quantity of gas. If the two reagents are exposed separately to strong sunlight and are then mixed, the decomposition goes on much more rapidly than if the mixture is exposed to light before separate insolation. The following numbers illustrate this fact; the measurements, which were made after the same intervals of exposure, show an acceleration of about ten p.c. in the latter case:—

	Gas disengaged.									
Liquids not insulated	0	24	52	64	83	93	100	107		
Liquids insulated for	0	24	58	70	91	103	110	117		
nine hours										
Ratio		1	1.11	1.09	1.10	1.11	1.10	1.09		

A remarkable point noticed in these experiments was that the addition of water increased the rate of action of the light. This anomalous effect may have been due to the partial decomposition of the ferric salt, as well as to the fact that the upper layers of the ferric chloride absorb much of the light and prevent it penetrating far into the liquid.

According to Amato (G. 34, 57), many reactions which are produced by sunlight are not really due to this agency. Amato considers that light only acts under certain determinate conditions of temperature, and that consequently there are limits of temperature within which light does not act in a chemical way. He found that a mixture of Cl and P, if cooled to  $-12^\circ$  could be exposed to the direct rays of the sun for hours without combination taking place. In this experiment care must be taken that the Cl is not exposed to the sun's rays before cooling, as insolation renders chlorine capable of combining with hydrogen even in the dark.

**INFLUENCE OF PRESSURE.**—Many substances when subjected to the influence of heat in a closed vessel, such for instance as calcic carbonate, ammonic carbamate, or paracyanogen, are decomposed or changed to an extent which is found to be limited, for a constant temperature, by the pressure of the resulting gaseous

products. When the pressure of the evolved gases has reached a definite value no further alteration takes place. If, however, the pressure is maintained below this limit, by allowing the gases to escape, complete decomposition results. The consideration of the influence of gaseous pressure in such instances belongs to dissociation (q. v.). There are, however, a few chemical changes known, other than those of dissociation, which occur only under considerable pressures, and others again which are prevented, or at least greatly retarded, by pressure.

Caillaud (C. R. 48, 395) found that, representing the amount of action between zinc and  $\text{HCl}$  of a definite strength under ordinary atmospheric pressure, by 10, the action was reduced to 4.7 under a pressure of 50 atmospheres, and under 120 atmospheres the amount of action in the same time was only .1. The amount of action between  $\text{HNO}_3$  and  $\text{CaCO}_3$  under pressures of 1 and 150 atmospheres he found to be as 11.09 : 1.

Beketoff (C. R. 48, 142) reduced solutions of silver nitrate and sulphate, and ammoniacal silver chloride, by hydrogen, under pressure—reactions which do not take place at atmospheric pressure.

By mere mechanical pressure Spring (B. 17, 1218) caused several of the metals, such as copper and lead, to combine with sulphur, and also brought about the formation of many alloys.

**CONTACT-ACTIONS.**—*Catalysis.* *Cyclical Actions.*—Catalysis, or contact-action, is the name given to a numerous class of chemical changes that are induced in certain chemical systems by a substance which does not itself undergo any permanent alteration, but which by its mere presence under suitable conditions brings about a re-arrangement among the molecules of the bodies with which it is placed in contact. The material which acts in this manner, without apparently being affected itself by the changes it induces, has been termed a catalytic or contact-agent.

According to the theory of Berzelius, who was the first to study this class of reactions, such bodies are possessed of a peculiar property or power which he termed 'catalytic force,' or the power to bring about chemical changes. Berzelius assumed this catalytic force to be of the character of an electrical force. It seems simpler, however, to regard such actions as being merely manifestations of the same property or power that is exhibited by all forms of matter undergoing chemical change, or the manifestation of the affinities of one kind of matter for another. It is reasonable to suppose that in every chemical system there is a tendency to undergo change of some definite character, such for instance as hydrogen and oxygen to unite, cane sugar and water to form glucose, potassium chlorate to give off oxygen, &c. The conditions under which the system exists may be such that the affinities are in a state of stable equilibrium among themselves. Every system may be regarded as having a weak point, or point of least resistance, at which an alteration will most easily take place. For instance, in the reduction of certain metallic oxides, the oxides are first reduced to lower oxides and then to the metal;

or, certain salts are decomposed when heated, but one phase of the change takes place at a lower temperature, or more easily, than another phase. It would seem probable, therefore, that if a suitable material were introduced into a chemical system, it might so react with certain constituents of the system as to upset the previous equilibrium to such an extent that what was before merely a tendency to undergo change would become an actual change, beginning at the point which before the introduction of the catalytic agent was the weakest point of the system. The catalytic agent may be regarded as tending to form, with one of the constituents of the system, a compound too unstable to exist under the conditions, which compound immediately breaks up, leaving the so-called catalytic agent in its original condition, free to react with a fresh portion of the system.

Contact-action would seem to be rather an ill-chosen term for this class of reactions, since all chemical combinations imply contact. It is also well known that many soluble salts if placed in contact with insoluble salts or pps. adhere tenaciously to these. A striking instance of this kind of contact-action is exhibited by metastannic acid. If a small quantity of this powder be shaken up with a highly ferruginous solution of aluminium sulphate, the ferric oxide in solution is seized upon by the insoluble metastannic acid, leaving a solution of aluminium sulphate in which scarcely a trace of iron can be detected.

From the evidence that exists relating to what is strictly known as catalytic action, if a word were necessary to distinguish this kind of change from ordinary chemical reactions, *cyclical action* or *cyclical change* would seem to be near the mark.

The instances that are known among gases in which the presence of a body brings about chemical action in an otherwise stable gaseous mixture seem to be explained by assuming that contact action merely causes a condensation of the gases upon the surface of the material that brings about their union. Faraday (T. 1834. 55) found that if a plate of perfectly clean platinum is brought into a mixture of hydrogen and oxygen, combination of the gases begins to take place, at first slowly, but at a gradually increasing rate, until combination occurs with explosive violence. This combination was considered by Faraday to be due to the condensation of the gases upon the metallic surface, whereby the molecules of oxygen and hydrogen were brought into such close contact that chemical union took place. The presence of small quantities of CO or CS<sub>2</sub> prevents the combination of the oxygen and hydrogen by aid of a platinum surface, although the metal is not found to lose its power if afterwards plunged into a pure mixture of the gases. Small quantities of such gases as H<sub>2</sub>S or HCl, however, so alter the platinum-surface that the metal is now incapable of effecting the combination of H with O. Other substances, such as charcoal, pumice, rock crystal, &c., act in a similar manner to, but less rapidly than, platinum. Platinum also brings about the combination of SO<sub>2</sub> and O to form SO<sub>3</sub>, of NH<sub>3</sub> and O to form HNO<sub>2</sub>, and H<sub>2</sub>O, &c.

Knowlton (B. 17, 1360; 18, 2808), when determining the vapour density of tertiary myristate, found that the dissociation-phenomena exhibited by the vapour of this body are influenced in a striking manner by the presence of many finely divided substances such as silica, magnesite, calcium sulphate, &c. The effects varied with the chemical, as well as with the physical, characters of the substances placed in contact with the vapour. To such a slight extent have these contact actions been studied that it seems as yet impossible to interpret them in the same way as those chemical actions which are here termed cyclical. Faraday's theory for the action of platinum in bringing about the union of oxygen and hydrogen by a mere condensation of the gases would seem to be the most reasonable explanation in the face of the facts at present known.

Examples of catalytic actions are known among liquids, which may be explained on the theory of cyclical change; such are the evolution of oxygen from a solution of a hypochlorite when warmed with cobaltous or manganic oxide, and the decomposition of hydrogen peroxide by manganese dioxide, finely divided platinum or silver, or by oxide of silver. The last case is remarkable, for here oxygen is evolved both from the silver oxide and from the hydrogen peroxide; to explain this, and a number of analogous reactions, Brodie (T. 140, 759) assumed that atoms of the same body may have an attraction for each other or be in a state of polarisation. Brodie expressed the reaction of  $\text{Ag}_2\text{O}$  with  $\text{H}_2\text{O}_2$  thus,  $\text{H}_2\text{O}_2 + \text{Ag}_2\text{O} = \text{H}_2\text{O} + \text{O} + \text{Ag}_2$ .

The change of cane sugar and water into glucose, and of ethereal salts and water into acids and alcohols, in the presence of acids which themselves remain unchanged, are other instances of catalytic action probably of a cyclical character (see AFFINITY, pp. 71 et seq.).

If potassic chlorate is heated alone it melts at about  $345^\circ\text{C}$ . and on increasing the temperature to about  $370^\circ\text{C}$ . oxygen begins to be produced. Many substances in a fine state of division when mixed with this salt cause an evolution of oxygen much below the temperature at which the chlorate decomposes when heated alone, and without the salt entering into a state of fusion. The substances which facilitate this decomposition do not themselves appear to undergo any chemical change. It is probable that the theory propounded by Mercer (B. A. 1842, 32) to explain analogous chemical changes is the true one, viz. that the material which facilitates the decomposition has a tendency to pass into a higher state of oxidation, and that an unstable compound is formed, but is decomposed at the temperature of the experiment. On this hypothesis the potassium chlorate is regarded as being decomposed at the lower temperature by the double effect of heat and the affinity of the contact substance—as  $\text{MnO}_2$ —for the oxygen of the chlorate. Heated by itself, potassium chlorate passes through an intermediate stage, in its decomposition with the formation of perchlorate; this intermediate stage is represented according to some chemists by the equation  $2\text{KClO}_3 = \text{KClO}_4 + \text{KCl} + \text{O}_2$ , but it appears to be more correctly expressed by the

equation  $10\text{KClO}_3 = 6\text{KClO}_4 + 4\text{KCl} + 8\text{O}_2$  (Teed, C. 1842, 248). If, however, manganese dioxide is heated with the chlorate, no perchlorate is formed; this fact may be explained and used as an argument in favour of Mercer's view, by supposing that  $\text{KClO}_3$ , when decomposed by itself forms  $\text{KCl}$  and  $\text{O}_2$ , and that the nascent ozone oxidises a second molecule of chlorate to perchlorate, whereas in the presence of  $\text{MnO}_2$  a higher but very unstable oxide of manganese is formed, and is almost simultaneously decomposed. The oxides which most markedly facilitate the decomposition of potassium chlorate are as a rule those the metals of which form several oxides. It is a well-known fact that the oxygen prepared from  $\text{KClO}_3$ , either by heating the salt, alone or mixed with  $\text{MnO}_2$ , liberates iodine from an alkaline iodide; this is usually considered to be due to a trace of free chlorine; lately, however, be occasioned by a little ozone that escapes decomposition by the  $\text{MnO}_2$  or the  $\text{KClO}_3$ .

Contact chemical action, whatever be its true cause, plays a highly important part in several industrial operations, as the inversion of cane sugar, the conversion of starchy matters into glucose, the decolorisation of sugar solutions by charcoal, and probably in the purification of waters by filtration through porous media. Formerly the great industrial processes of fermentation in the formation of alcoholic liquors were referred to this cause, but it seems now certain that such changes are phenomena connected with organic life and not with those of unorganised matter.

(For a theoretical consideration of catalysis see Mendelëeff, B. 19, 456.)

A consideration of the facts that are known relating to chemical change shows that in the study of the subject not only must the kind of quality, and the mass, of the reacting matter, be taken into account, but attention must also be given to the intrinsic forces that come into play, as well as to the motion of molecular or atomic motions. It is not at present so much the relative values of these forces that one desires to know, in whatever way they may be measured, as the circumstance under which the forces act, or are modified in their action. It has been seen that all atomic structures are possessed of relative degrees of stability, as is shown when submitted to the action of physical agencies, or when they play an active part in chemical systems, this stability being due to the interaction of the affinities holding the structure together. These forces or affinities offer different degrees of resistance to the action of different agencies, and it would seem to be only by the study of such influences that a rational conception of the nature of chemical action will be arrived at.

That the ultimate constituents of matter—the atoms or molecules—are in continual motion, the interdiffusion of gases, and of salts in solution, seems to prove; and the fact that, in a chemical system undergoing change, such change is more or less gradual, taking fractions of seconds or whole years to be accomplished, seems to offer conclusive proof that the atomic constituents are in a continual motion of interdiffusion. But whether or not the change going on in a chemical system is brought about by simple

collisions among the moving molecules cannot be asserted. For instance, anhydrous alcohol and acetic acid, when mixed in equivalent proportions react upon each other at ordinary temperatures with extreme slowness; in fact, it takes months to accomplish what at 100° requires only minutes, and yet it is highly probable that very many more collisions occur between the alcohol and the acid molecules than the rate of change would lead us to conclude. It may be that in these and similar cases the molecules of the two constituents of the system must be moving with a definite velocity if chemical action is to occur. But the kinetic theory of gases teaches that in a space of uniform temperature some molecules have high and others low velocities, and that the ratio between the numbers of molecules having high and those having low velocities varies with the temperature; consequently in chemical change which occurs may be but a process of selection among the molecules according to the velocities they possess, those with velocities below a certain limit colliding, but not reacting chemically with, each other.

As chemical reactions are generally formulated, the phenomena of change are for the most part at present viewed only in the light of the distribution of certain masses of matter of various kinds, and no cognisance is taken of the changes in the energies of the systems as these pass from the initial to the final states. In the blank that is at present occupied by the sign '=' lie all the real phenomena of the science of matter. Attempts have been made to fill up this blank by the investigation and measurement of the heat-disturbances that arise when a chemical system passes from the state represented by one side of the equation to that represented by the other side. By virtue of the inherent forces or affinities, as well as by the particular motions of the ultimate particles or atoms of matter, all substances may be looked upon as possessing a certain definite amount of energy, potential as well as kinetic, and consequently as capable of performing a definite amount of work. The tendency of the constituents of a system is invariably towards a state the attainment of which involves a degradation of energy; in other words the total energy of the system tends to pass from a higher to a lower level. For the general inferences that have been drawn from the study of thermal phenomena bearing on the applications of the laws of energy to chemical change reference must be made to the section on THERMAL PHENOMENA of the article PHYSICAL METHODS USED IN CHEMISTRY.)

It is much to be desired that a classification of the elements, or, what seems next to impossible, of their compounds, should be attempted, based

upon some particular dynamical property which should include not only the conception of mass but also the conceptions of time and work; it is evident, however, that the difficulty lies in the kind of phenomena to be observed and measured. Mills (*Proc. M. S.* [5] 1) has propounded certain ideas relating to chemical phenomena, making motion the basis of the science; and he considers that chemical substances should be valued not for what they are conceived as being, but for what they are capable of doing. Doubtless, however, the being as well as the doing must be considered together. The masses of various bodies necessary for the performance of unit of work Mills terms the dynamical equivalents, or the 'bergmannics,' of the respective bodies; these may vary according to the sort of doing, or work, the several substances are employed to effect; such as the power of various acids to invert sugar, or to decompose ethereal salts, the precipitability of salts, the coefficients of diffusion, &c., &c. For many valuable determinations of dynamical effects of substances in inducing or accelerating chemical changes, see the work of Ostwald. For a full account of this work v. the article AFFINITY.
